QUEENSLAND COAL MINING BOARD OF INQUIRY

Coal Mining Safety and Health Act 1999

Establishment of a Board of Inquiry Notice (No 01) 2020

Before:

Mr Terry Martin SC, Chairperson and Board Member

> Mr Andrew Clough, Board Member

At Court 17, Brisbane Magistrates Court 363 George Street, Brisbane QLD

On Thursday, 18 March 2021 at 10am (Day 19)

© Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 2 THE CHAIRPERSON: Yes, Mr Hunter. 3 4 MR HUNTER: May it please the Board, I call Sean Muller. 5 <SEAN MULLER, sworn: [10am] 6 7 <EXAMINATION BY MR HUNTER: 8 9 MR HUNTER: 10 Q. Mr Muller, will you tell us your full name? 11 12 Α. Sean William Muller. 13 14 Q. You work at Simtars? 15 Α. Yes. 16 Q. What position do you hold there? 17 I am acting senior analytical chemist. Α. 18 19 20 Q. I'll just ask you to keep your voice up nice and loud so we can hear you. So you're an acting senior analytical 21 Do you have a Bachelor of Applied Science degree? 22 chemist. Α. Yes. 23 24 25 And did you major in chemistry and industrial Q. 26 chemistry? Α. Yes. 27 28 Did you achieve that qualification in 2008? 29 Q. Yes, I think so. 30 Α. 31 32 Q. How long have you been working at Simtars? Over 10 years, maybe 10 to 11 years. 33 Α. 34 And over that period of time, what have you been 35 Q. doing? 36 37 Mainly gas analysis, particularly relevant to Α. underground coal mines, a lot of that being using gas 38 chromatographs, tube bundle systems, gas monitors. 39 40 41 Q. I'll get you to explain gas chromatographs to us in Do you have exposure to tube bundle systems? 42 a while. 43 Yes. Yes, we have a mobile laboratory and it has Α. a tube bundle system that we regularly use. 44 45 46 THE CHAIRPERSON: Q. Mr Muller, I'm sorry, but you're going to have to keep your voice up throughout the whole 47

giving of evidence, because it's really very difficult to 1 hear, so please bear that in mind. 2 Yes, no worries. 3 Α. 4 MR HUNTER: 5 Thank you. 6 7 Q. So you were saying that there's a mobile laboratory that Simtars has? 8 Α. Yes. 9 10 Q. What does that mobile laboratory comprise? 11 It has a tube bundle system, and it has room for two 12 Α. 13 gas chromatographs. 14 Have you been responsible for setting up and running 15 Q. 16 and decommissioning that mobile gas laboratory? Yes. 17 Α. 18 19 Q. Have you got experience in responding to mine emergencies, including spontaneous combustion events? 20 Α. Yes. 21 22 And have you personally been involved in the response 23 Q. to significant events that have involved extensive loss of 24 25 production and equipment? Yes, that's correct. 26 Α. 27 Can you tell us about some of those, please? 28 Q. Well, the first emergency I responded to in 2010 was 29 Α. Pike River. I was deployed there to run the gas 30 31 chromatograph on site and to train others to run the gas chromatograph and also to do up reports, simple reports, 32 and help with sampling. 33 34 Yes, after that? 35 Q. After that, Carborough Downs was another deployment 36 Α. 37 that we had where we used the mobile lab for months, using the tube bundle system and gas chromatographs to analyse 38 39 samples on that mine site. 40 What had happened at Carborough Downs? 41 Q. I'm not a hundred per cent sure what happened at 42 Α. 43 Carborough Downs. By the time we were deployed, I suppose the problem had already manifested, and back at that time 44 I was more involved in simply ensuring the analysis was 45 46 correct rather than getting involved in the cause. 47

Were you deployed to North Goonyella in 2014? 1 Q. Yes, that's correct. 2 Α. 3 In brief terms, what was the nature of that incident? 4 Q. It was a seal-up of a longwall, and I provided 5 Α. 6 a second gas chromatograph on site to assist with the analysis. 7 8 But what had occurred underground in relation to the 9 Q. seal-up that caused you to be deployed there? 10 Again, not a hundred per cent sure of what the cause 11 Α. of that incident was. I do remember there being 12 13 significant spontaneous combustion gas indicators there 14 that prompted that, that they were looking for. 15 16 Q. Were you deployed to Narrabri in 2018? Yes. 17 Α. 18 19 Q. What sort of incident was that? Did that involve spontaneous combustion? 20 Yes, that was a spontaneous combustion incident. 21 Α. 22 Were you also deployed to North Goonyella for a second 23 Q. time, in 2018? 24 25 Α. Yes, that's correct. 26 And on that occasion there was a spontaneous 27 Q. 28 combustion and fire? 29 Α. Yes, yes. 30 31 Most recently have you been deployed to Moranbah North Q. mine in the last few months, or weeks? 32 I was also, before that, deployed to Grosvenor Yes. 33 Α. in June. 34 35 June of last year? 36 Q. 37 Α. Yes. 38 39 Q. Moranbah North was this year? 40 Α. Yes. 41 Are you familiar with NATA, the National Association 42 Q. 43 of Testing Accreditation? Yes, or "Authorities", possibly. 44 Α. 45 46 Q. Do you hold any qualifications with respect to NATA? Yes, I'm an approved signatory for our NATA accredited 47 Α.

methods on site involving gas analysis at Simtars. 1 That could involve the gas chromatograph analysis or the 2 calibration of instruments, for example hand-held gas 3 monitors or infrared analysers used in a tube bundle 4 5 system. 6 7 Q. Does your role also involve the delivery of training programs for coal mine workers? 8 Yes, that's correct. I deliver gas chromatograph 9 Α. training and spontaneous combustion training in terms of 10 the gas analysis side of things there. 11 12 13 Q. For how long have you been delivering those training programs? 14 Gas chromatograph, most of 10 years, and the 15 Α. 16 spontaneous combustion from about 2014, I'd estimate. 17 The mine personnel to whom you deliver this training, 18 Q. 19 particularly about the use of a gas chromatograph, what role or roles do those coal mine workers generally occupy? 20 It could be - it's normally a variation. 21 Α. Often it 22 would be control room operators or technical-services-type It could also be deputies, and in some cases it 23 people. could be miners from underground that do that for some 24 25 reason. 26 Do the people that you train generally already have, 27 Q. for example, qualifications in chemistry? 28 All of the operators we train are staff or 29 No. Α. workers at the mine site, and as far as I know, I haven't 30 31 come across anyone I've trained with a chemistry degree before. 32 33 34 Q. We heard a little bit of evidence yesterday about gas chromatography, but it sounds like you might be the person 35 to ask to explain it to us in terms that we can understand, 36 37 please. Α. Yes. 38 39 40 Q. Could you tell us what a gas chromatograph is and what it does? 41 A gas chromatograph is a scientific instrument which 42 Α. 43 analyses gases. The reason it's called a gas chromatograph is actually because it runs on gas, not necessarily because 44 45 it analyses the gas. 46 47 It's got columns within the instrument, which you

could imagine as being a hollow capillary with some sort of 1 packing, if you'd imagine - they call it a molecular sieve, 2 so you could imagine it being some sort of porous 3 structure. A gas is passed through there called the 4 carrier gas, which provides the instrument with the 5 6 pressure needed to separate the gases out. 7 When the samples are introduced into that stream, 8 they're separated out before they pass over a detector. 9 What this looks like on the output is you get a graph, and 10 it's a time graph where you've got peaks that come out at 11 certain times. Those peaks correlate with the amount of 12 13 time it took for the sample to pass through the column. In that respect, too, the sample has been separated apart, so 14 each component of the gas is being analysed individually 15 16 rather than at the same time as other components. 17 The height, or the area of the peaks, represents the 18 19 concentration. So you can tell which gas is which by the time it comes out, and you can tell how much there is by 20 the size of the peak. 21 22 23 Q. So do you measure the area under the curve? Α. 24 Yes. 25 26 Q. How do you know which analyte you're looking at as the results come out? 27 28 Α. So we deliver a span gas for calibration, and we know 29 what's in that span gas. From prior research and set-up, we know what order those gases come out in. So when we put 30 that span gas through, we can identify the precise times 31 that those components are coming out. What we do is we set 32 a - it's called a retention window, where you give a range 33 34 for anything to come out in that particular time would correlate with that particular gas. 35 36 37 I'll take you to a graph in due course, but how Q. sensitive is a gas chromatograph? 38 It depends on what gas you're trying to analyse. 39 Α. A gas chromatograph uses a thermal conductivity detector, 40 so different gases have different thermal conductivities. 41 As an example, carbon monoxide is not particularly 42 43 sensitive on a gas chromatograph compared to an infrared analyser, but for something like carbon dioxide, that might 44 be very sensitive; or other gases, for example hydrogen and 45 46 ethylene, they're very sensitive as well. 47

Is there, though, a limit below which you can't 1 Q. 2 reliably say that a particular gas or a particular quantity of that gas is present? 3 We generally have a limit of 4 Α. Yes, that's right. detection associated with the different gases so that we 5 6 can confirm that at that particular concentration we will It doesn't necessarily mean the concentration 7 see a peak. of that peak is exactly that concentration, and certainly 8 9 below it. However, we do know that we can see it at that concentration, and often you can see it below that 10 concentration as well. But the way we do our limit of 11 detection, we have a relative standard deviation threshold, 12 and for it to pass that, you know, we do a test to make 13 sure it can meet that threshold. 14 15 16 Q. I'm going to ask you quite a bit about ethylene. 17 Α. Yes. 18 19 What's the generally accepted, if there is one, limit Q. of detection for ethylene on a gas chromatograph? 20 We would normally do a limit of detection for 1 ppm 21 Α. 22 for ethylene. However, that's not necessarily - you know, 23 because of the capabilities of the instrument, we've also got gas mixing equipment. We have to make sure that our 24 gas mixing equipment can reliably mix something. Mixing 25 below 1 part per million of ethylene is difficult. 26 So because we can mix 1 part per million, and that's a good 27 28 threshold value for that, we will make sure we get a limit of detection for 1 ppm of ethylene. 29 But below that, you still quite often see a peak - in fact, half a ppm of 30 31 ethylene is quite clear to see, and below that, it's often There is a threshold possibly below 0.2 or 0.1 32 visible. where it becomes very difficult. 33 34 Also, at, say, levels below 0.1 and, you know, more 35 relatively as you move towards zero, say if you're getting 36 37 a result of 0.2, that doesn't necessarily mean that's 0.2. That's below the limit of detection and we can't guarantee 38 that that would be the level. It could be 0.3 or 0.4. 39 40 41 So what sort of skill is required to detect ethylene, Q. for example, at these low levels? 42 43 Because the ethylene is at such a low level in that Α. the computer software cannot easily identify a peak - and 44 this can happen with other gases as well, for example 45 46 carbon monoxide - the GC operator is trained to zoom in, is 47 our term, on the baseline, where they magnify the response

1 on the graph until they can get a clear idea or a more 2 clear idea of whether that peak in fact is present or not. 3 4 Q. Obviously we're talking about the state of science as it is today. Has it in the past been suggested in 5 6 scientific literature that the limit of detection for 7 ethylene, for example, using GC analysis, is in fact higher than 1 part per million? 8 9 I don't recognise that. In fact, I've heard stories Α. of different types of GCs being able to see ethylene at 10 lower levels than 0.1 or 0.2. I am not familiar with every 11 12 different type of GC. GCs are not just something that's 13 used on a mine site. A GC could analyse all sorts of It could be heavy metals, toxins, drugs - there's 14 things. a lot of GCs that do a lot of different jobs. 15 So to be 16 able to say what the limit of detection is on any GC anywhere, I wouldn't be able to give you that answer. 17 18 19 Obviously what you are looking at is the data that was Q. produced by the mine's GC, not your own. 20 Mmm-hmm, yes. 21 Α. 22 23 What you've just told us is that the limit of Q. detection is GC specific, that is, specific to individual 24 instruments or types of instruments? 25 26 Α. That's correct. Different types of instruments with different columns. Even instruments with the same column 27 28 and the same set-up, at these low levels there can be individual differences between instruments, and that would 29 be expected to an extent. 30 31 What do you know about the specific instrument that 32 Q. was being used at Grosvenor that produced the data that you 33 34 reviewed? We validated that GC to the same specifications as all 35 Α. of our GCs in terms of the limit of detection at 1 ppm. 36 37 So when you say you validated that GC, how did you do 38 Q. that? 39 40 Α. We do tests in the laboratory where we mix gases and we challenge the GC with them to ensure that the GC is 41 responding as we expect. 42 43 44 And that was done with respect to the GC at Grosvenor? Q. 45 Α. Correct. 46 47 Q. All right, I'll probably ask you some more questions

TRA.500.019.0009

about ethylene in due course, but in a general sense, as we 1 will hear, you found quite a number of sub 1 ppm detections 2 for ethylene in samples that had been taken at various 3 4 locations? Yes, that's correct. 5 Α. 6 7 Q. How confident are you, given what you've just told us, that those detections are real, in the sense that you are 8 actually seeing a detection for ethylene as opposed to 9 something that was so small as to not be able to reliably 10 said to be ethylene? 11 12 I'm very confident. We can tell by the amount of Α. 13 noise on the baseline either side of the peak in question as to what the noise level is from the response, and if 14 that peak is significantly above that noise level, then 15 16 it's fairly straightforward to see with your eyes that there is something there. 17 18 19 It is usually the same width and it is in the same spot, and it's often repeatable. So if you had a sample 20 with ethylene in it, and then you ran one without, and then 21 22 you ran another one, the same one, you know, you'd usually 23 see the same thing. 24 25 Can I ask you about the sources of ethylene. We heard Q. a suggestion yesterday that timber, presumably the 26 combustion of timber, might be something that would produce 27 28 ethvlene? The combustion of timber? 29 Α. 30 31 Q. Yes. Well, I'm sure the combustion of timber would. 32 Α. I think the question could be timber that's not combusting, 33 34 just timber that's present. 35 Does timber of itself give off ethylene? 36 Q. 37 I'm not - I haven't seen any conclusive research, Α. although I have seen preliminary ideas that wood can give 38 off ethylene. In my experience I have seen that before. 39 40 The times I've seen it has been at very low levels and it has been in longwall panels that have been sealed that have 41 no longer ventilation, where the ethylene is allowed to 42 43 accumulate without being diluted, until the point where it's detectable, and in that case there was also no carbon 44 45 monoxide or hydrogen. 46 47 Q. What's the significance of the absence of carbon

1 monoxide and hydrogen? Well, carbon monoxide is one of the primary indicators 2 Α. of spontaneous combustion. As oxidation increases, carbon 3 monoxide increases, hydrogen increases, ethylene increases. 4 If I was seeing low levels of ethylene, I'd also expect to 5 6 see carbon monoxide to go with it and possibly hydrogen. That's not always the case. I have seen instances of 7 spontaneous combustion with relatively low levels of carbon 8 monoxide compared to ethylene, and I suspect that will be 9 more of an issue with dilution and specifics of what is 10 happening with that heating. But generally, the more 11 carbon monoxide you see, the more ethylene you're likely to 12 13 see. 14 15 Q. Are you familiar with some studies that were done with 16 respect to detections of ethylene at the Crinum North mine? I'm not particularly familiar with it, but I do recall 17 Α. that that's the occasion where I have seen that and that 18 19 I believe that's what it was. 20 The amounts being detected in that instance were 21 Q. 22 sub 1 ppm? Α. I believe so. I can't recall, but I assume so. 23 24 25 Was that a case where the mine had recovered Q. a longwall and used timber cribs to support the roof? 26 I'm not aware of all the details, but I assume, if 27 Α. they're suspecting that it's from wood, that that would 28 make sense. 29 30 31 Can we go, then, to the PowerPoint, please, Q. Mr Operator. Slide number 2, does that identify the 32 significant locations from which, as you understand it. bag 33 34 samples were taken? That's correct. That diagram is missing a few of the 35 Α. gas wells, but for the most part, that's where the samples 36 37 were taken from that I've analysed. 38 39 Q. You've mentioned the goaf stream here? 40 Α. Yes. 41 42 Q. You've said that obviously moves with the longwall 43 face? 44 Α. Yes. 45 46 Q. You've also referred to 96 chock? 47 Α. Yes.

1 2 Is that an area that became significant after the Q. 3 events of 6 May? That's correct, from memory, it was around the 15th, 4 Α. possibly the 17th of May where samples started coming from 5 6 I think there might have been a tube set-up that location. 7 there that the samples were being drawn from. 8 9 That data suggested that there was a heating Q. 10 occurring? Yes, and also it would be - maybe not my expertise, 11 Α. 12 but I wouldn't expect to see a tube halfway along the face. 13 14 We've also got a number of tube bundle locations here Q. at the rear of the goaf. You analysed bag samples that 15 16 were taken from those locations, or some of them? Yes, that's correct, there were bag samples being 17 Α. taken from 38 cut-through. I think there might have been 18 19 one from 37 as well, or a couple. All of those seals 20 around the back. 21 22 Q. The samples that were taken from there, does the 23 taking of a bag sample in a location such as that involve a person physically going there, or is it done remotely 24 25 from the surface using a bag? It would be done physically in person. 26 If there is Α. a tube there, it is possible to take the sample from the 27 28 tube. I think there was a tube at 38 cut-through, but typically samples would only be taken from tubes if they 29 needed to be and they couldn't access that area 30 31 underground. 32 I'm going to take you to a summary of some of the 33 Q. significant sample results that included detections for 34 ethylene. Can I ask you, please, to tell us about the 35 significance of ethylene in terms of monitoring for 36 37 spontaneous combustion? A lot of the gas evolution tests that have been done 38 Α. over the years as part of research or work done for a coal 39 40 mine seems to indicate that ethylene appears at somewhere around 100 degrees. For some coals it could be before 41 then, and for some it could be after that, maybe 120 or 42 43 But in general, as a simplification, ethylene is 140. 44 likely to occur around 100 degrees or higher. 45 46 Q. So the presence of ethylene, then, in gases coming 47 from the goaf would suggest what?

A heating or a spontaneous combustion developing or -1 Α. ethylene could possibly even represent a much more advanced 2 heating or a fire, even. Ethylene will come from a fire as 3 well. 4 5 6 Does the amount of ethylene tell you anything about Q. the severity of what's going on? 7 Well, generally you'd expect the ethylene to increase 8 Α. with increasing temperature. But it could also be the size 9 of a heating which may influence the amount of ethylene 10 that's being detected. 11 12 13 Q. So how important, in your view, is it that a mine 14 monitor for ethylene? I think it's very important. Often when ethylene is 15 Α. 16 detected there's also associated higher CO, as I was saying previously, and I think it's a warning sign that something 17 isn't quite right and it should be responded to or 18 19 investigated, at the least. 20 You've seen the spontaneous combustion TARP for 21 Q. 22 Grosvenor? Α. Yes. 23 24 25 And, in particular, you've seen that portion of the Q. TARP that relates to the longwall return? 26 Α. Yes. 27 28 29 The level 1 triggers that are specified don't include Q. ethylene? 30 31 Α. No. From memory, no. 32 In your view, should a mine monitoring the longwall 33 Q. return include a TARP trigger for ethylene? 34 However, by the time you are detecting 35 Yes. Α. significant ethylene in the tailgate, your CO make would 36 37 probably be high enough that there would be all sorts of other indicators. I would expect a goaf stream sample to 38 be particularly relevant for ethylene, because you'd be 39 picking up more of a concentrated sample before it gets 40 diluted in the tailgate. 41 42 43 Q. So if you're monitoring for ethylene - we know that there was a monitoring point at 3-4 cut-through here that 44 was about 4 kilometres from the face. Is there much point 45 46 monitoring for ethylene at that point? Well, obviously if there is ethylene at that point, 47 Α.

that's a big concern, so it should be picked up and 1 identified. I guess what I'm saying about the TARP is 2 that, you know, I'd expect if you saw that much - if you 3 saw 1 part per million of ethylene in the tailgate, I'd 4 expect all of those other triggers to be triggered, 5 6 anyway - or at least some of them. 7 You reviewed the bag sample data for the goaf stream, 8 Q. because there were regular samples being taken at 9 10 Grosvenor - yes? Yes. Α. 11 12 13 Q. But there was a point where the taking of samples was 14 less regular than it had otherwise been? There was a few instances where a few samples 15 Yes. Α. 16 were missed throughout the period, but there was a particular time where some, or a few consecutive ones, 17 were not taken. 18 19 20 You put together - and this is an extract from it -Q. a table that identified the various significant sample 21 22 results? Α. 23 Yes. 24 25 And you've seen this document and checked that it Q. 26 accords with your figures? Α. Yes. 27 28 Does it show in this case for the goaf stream the 29 Q. significant results that you identified? 30 31 Yes. So anything that's either higher CO compared to Α. other samples either side of it or around from that 32 location, I guess, anything that's got a bit of elevated CO 33 34 or that's detected ethylene or that's got a Graham's ratio over the mine's TARP level, I've identified that, or, you 35 know, if there's something else, for example a CO/CO2 ratio 36 37 that might be in a sample, I've added those samples into this list. So this list is not a comprehensive list of 38 samples. There will be two samples taken from this 39 40 location every day. 41 We can see beside the results for ethylene, I think 42 Q. 43 all of them on this page, there's an asterisk. Does that depict or does that indicate that in each instance, the 44 person who operated the gas chromatograph or who reviewed 45 46 the data didn't note down a detection for ethylene? That's right. I've looked at the data as it's been 47 Α.

1 processed and added in to the trending software that goes 2 If I've come across some ethylene that was not with it. originally identified, I've put it in this table and I've 3 put an asterisk next to it to differentiate the ones that 4 had been detected by us compared to the ones that were 5 6 detected by the mine.

7

31

43

One of the ones where you did identify ethylene was 8 Q. I'm 9 for 19 March - I think there were two on that date. just going to jump forward a number of slides. 10 Is this. which is slide 11, part of the GC data that's been output 11 12 for I think it's the second sample taken on 19 March? 13 Α. Yes, that's what we would call a chromatogram, so that is a zoomed-in view. Normally, the initial view the 14 15 operator is presented with is nowhere near as clear as 16 that. They will have to magnify that view several times, possibly five, ten times if necessary, until they can see 17 that level of noise in the baseline, and then they can 18 differentiate a peak from that baseline, if there's one 19 there. 20 21

22 This can be very difficult to do at low levels of ethylene. It's something that gas chemists from Simtars, 23 which would regularly be involved with looking at these 24 types of levels of ethylene, would be very practised with 25 and proficient at. But an operator on a mine site might 26 not see ethylene very often or they might not run the gas 27 chromatograph very often, and because it is a difficult 28 thing to do, it's not particularly surprising that they 29 might miss some. It's ideal that they would identify it. 30

32 Q. Does the gas chromatograph, in particular the one at Grosvenor, automatically identify the major compounds, 33 34 major analytes?

Yes, that's right. Anything, say - on that picture 35 Α. there we've got the carbon dioxide, that peak, you know, it 36 37 goes right off the top of the screen. You can't see the That's easily big enough for the software to -38 top of it. it draws that green line from the start to the end of the 39 peak, and that's how it determines where the peak starts 40 and stops, and the area under that curve above the green 41 line is how it determines its concentration. 42

44 So with this ethylene peak there in the middle of the screen, that would - I'd say that is under the threshold of 45 46 what the instrument will be able to detect by itself, so that green line would not normally be there. That red 47

.18/03/2021 (19) S W MULLER (Mr Hunter) 1734 Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

window would be pink, which would indicate there is no gas 1 2 being detected there, but it is up to the operator to manually zoom in and confirm for themselves whether or not 3 there is ethylene there. So the gas chromatograph is 4 a very manual process. It's not like another gas monitor 5 6 which just gives you an automatic readout. This is very 7 visual, very manual, and it's very time intensive for the operators, and I quess that's the nature of it. 8

9

25

32

One of the questions, I suppose, consistently with 10 Q. what I was asking you earlier, is how do you tell a genuine 11 result from what might just be background noise? I'll just 12 13 zoom in on that section of the slide. How there do you differentiate between the noise and the actual? 14 To the left and to the right of where that green line 15 Α. 16 starts and stops, you can see a little bit of - what would you call it - texture in that line. It's not a complete 17 straight line. That's the noise from the response of the 18 19 detector. So we can see to the left and the right of it, and also if you drew a line from the bottom up to the top 20 there, a straight line, it would be in line with that 21 22 noise. So we can see that that ethylene peak - it sticks 23 up above that noise and it also sticks up above the gradient of that baseline. 24

Different GCs have different gradients of baselines, too. You know, sometimes I suspect that's why it can be difficult to determine whether it's a peak or not, because the baseline is already going up on an angle like it is there, but you can see that it does - the response is larger than the noise.

I'll just zoom in on the top left-hand corner, which 33 Q. 34 shows in the second line the place where the sample was taken, and there's two names there - Michelle Brunker and 35 Do you know whether one of those names 36 Glen Perry. 37 identifies the person who took the sample? If you don't know, tell us. 38 Looking at that, it looks to me like Glen has taken 39 Α.

the sample, as that's part of the sample description, and
normally a deputy's name would be written on the sample if
it was taken.

Q. And it's common for the deputy to write other
information pertinent to the sample as well?
A. Yes, that's right. They might have velocity
measurements or temperature or gas detector - they often

1 write hand-held readings from their gas detector where 2 their sample was taken. 3 4 Q. It there tells you that it was taken at 12am on 19 March 2020, and there were diesels in the panel? 5 6 Α. Mmm - hmm. 7 What's the significance of that notation? 8 Q. Well, often false alarms are detected underground, 9 Α. particularly in the tube bundle and the real-time system, 10 if a diesel is nearby to the sampling point, because 11 a diesel has an exhaust which might give out carbon 12 13 monoxide and might set off the alarm when it's not a true 14 alarm. 15 16 I suspect that the deputy has identified that there's diesels in the area, and, looking at that, the carbon 17 monoxide is 111, so he may have written down there, you 18 19 know, in case that had anything to do with that carbon monoxide reading, or maybe just to note that for reference. 20 21 The other entries are "cutting", the barometer 994 and 22 Q. falling, and the "wet and dry" - is that the temperature, 23 wet and dry bulb temperature? 24 I believe so. I'm not familiar with how to take those 25 Α. 26 measurements underground or exactly what they do with them. 27 28 Q. All right, we'll go back to the data. We now know that that was taken at midnight on the 19th, so we can see 29 there the table includes data for midnight on the 19th with 30 CO at 88 parts per million, and 0.26 parts per million for 31 ethylene? 32 Α. Yes. 33 34 Does a diesel exhaust emit ethylene? 35 Q. Oh, I'd say, in general, by the time it dilutes to any 36 Α. 37 significant extent, for practical purposes, no. I could imagine if a diesel engine was not operating very 38 efficiently, maybe there could be some ethylene or ethane 39 in the exhaust, but I would - in most cases, I would expect 40 a bit of extra CO from the diesel. 41 42 43 But on that note as well, it says there's diesels operating, but no diesels go in the goaf, so maybe they 44 were on the maingate side of the goaf and maybe the deputy 45 46 suspected that some of the CO could be going into the goaf and that's why that note was written, but I can't be sure. 47

TRA.500.019.0017

1 2 The one immediately below that identifies data for Q. 20 March, and you've noted in notes on the right-hand side 3 that the bottom sample contained 5.4 per cent methane? 4 Sorry, which sample was that? 5 Α. 6 7 Q. This is the second one on 20 March. 20 March. 8 Α. 9 Do you see that here? 10 Q. Α. Oh, yes, yes. 11 12 13 Q. There's no ethylene in that sample, but some was picked up in the sample earlier in the day? 14 15 Α. Yes. 16 The calculation for Graham's ratio was 0.95. Is that Q. 17 a significant figure for Graham's ratio? 18 19 Yes, that is a significant figure. I believe in this Α. case it's not quite accurate, because if there really was 20 a Graham's ratio of that high, maybe I would expect there 21 22 to be more samples with that, with a number like that, and in fact I think further on in my report I've gone through 23 and I've re-analysed all of the Graham's ratios to the best 24 of my ability using fresh air reference points and the most 25 optimal way of determining that, and I don't think that 26 sample was really 0.9. I think it was much lower than 27 28 that. But the GC can overestimate Graham's ratio in the presence of methane, higher levels of methane. 29 30 31 Later in your evidence, we'll hear about some methane Q. free calculations that you've done to remove the effects of 32 methane dilution? 33 34 I can't do that for the Graham's ratio. That's more Α. of, you know, the CO data from the gas wells in particular. 35 36 You also tabulated the readings from the goaf seals, 37 Q. and that's the next slide, slide 5. 38 Α. Yes. 39 40 41 You did note on the page that we just saw in a number Q. of areas where the CO/CO2 ratio was above 0.02, or was 0.02 42 43 or above? 44 Α. Yes. 45 46 What was the significance of noting a CO/CO2 ratio of Q. 0.02 or above? 47

1 Α. Well, textbook values for CO/CO2 ratio generally start 2 at 0.02 as the level that may be above normal. Gas evolution tests would also have some CO/CO2 ratios. 3 I've 4 chosen, I suppose, a fairly conservative level there, and that's particularly based on the presence of the carbon 5 6 dioxide as a seamgas. CO/CO2, you're comparing the amount 7 of CO generated compared to the amount of CO2 generated. But because this ratio was done on the raw gas results, the 8 CO2 from the sample will cause that ratio to be vastly 9 So if that threshold for the textbook 10 underestimated. value has been reached with the influence of the seamgas, 11 12 I've put that as "note". 13

Q. You've seen the same TARP that I talked to you about
before - that is, the TARP for spontaneous combustion in
the active goaf with the sampling point in the longwall
return?

18 A. Yes.

19

33

And you've seen that it has as its normal state, 20 Q. according to the TARP, a CO/CO2 ratio of less than 0.2. 21 What do you say about having a normal state for a TARP for 22 23 the longwall return where the CO/CO2 level is 0.2? I don't really understand that. When I first looked 24 Α. at this data, or the TARP, when I first saw the TARP, 25 I thought maybe that was a typo and it was supposed to be 26 The only reason I can think of having a threshold 27 0.02. 28 that high would be specific to some sort of gas monitor, like a real-time sensor for - with a CO2 sensor that could 29 drift out of correct response and give some sort of alarm 30 31 not based on the extra CO but on an under-reporting of CO2 32 or something, but that seems very detector based.

I suppose there would be one of those detectors in the tailgate, but for the purposes of the actual gas concentrations expected in the tailgate, I think you would need a lot of CO to trigger 0.2, and I think that if you had that much CO, your CO make alarm would be also a problem, and that TARP would not really alert anyone to anything quicker than any of the other - well, you know.

Also, the data from the GC results shows that in the lead-up to June, that trigger is not reached, despite there being obvious and problematic spontaneous combustion. So from the gas chromatograph results at least, that's not a relevant number.

TRA.500.019.0019

So that TARP trigger of 0.2, which, according to that 1 Q. TARP, if you've got a CO/CO2 ratio of less than 0.2, 2 everything's normal - that point of 0.2 wasn't reached even 3 before the explosion that occurred on 8 June? 4 Not on the GC data, I'd imagine not on the tube bundle 5 Α. data as well. 6 I just can't remember off the top of my head 7 about the tube data. 8 9 We will come to that. And it certainly wasn't reached Q. 10 prior to the events of 6 May? Α. No. 11 12 13 Q. This is back to slide 5. You were talking before about whether or not these hits for ethylene were picked up 14 by the operator. We've only got the ones for 31 March and 15 16 4 April with asterisks beside them. Does that indicate whoever was operating the GC or reviewing the data did spot 17 these small amounts of ethylene? 18 19 Yes, that's right. If it doesn't have an asterisk Α. beside it, it indicates that the operator identified that 20 themselves. 21 22 Similarly if we go to the results for the goaf seal at 23 Q. 39-40 cut-through, which is at the back left of the goaf, 24 25 and the one on the maingate side at 38 cut-through, in particular the latter, we can see that whilst there were 26 some that were missed, there were several that were picked 27 28 up? 29 Yes, that's right, and you can note with those samples Α. as well, they have relatively high CO even compared to the 30 31 other samples that I'd shown in the goaf stream on the earlier table, so 147, 193 ppm CO. I'd imagine that was 32 associated with some sort of TARP and they've identified 33 34 the ethylene to go along with those samples as well. And there's also CO/CO2 ratios that exceed the 0.02, and some 35 of those Graham's ratios are above 0.3, so you can see the 36 37 higher or the more of those indicators that are present, they all seem to go together. 38 39 40 So does that suggest to you that those detections, Q. say, for 22 April for ethylene were genuine detections? 41 Yes. Α. 42 43 44 Did you undertake the same exercise with respect to Q. data from various of the goaf wells? 45 46 Α. Yes. 47

Starting with well 3 - we've got on this page wells 3, 1 Q. 4.5 and 6.5 - there were a number of hits for ethylene? 2 Yes. that's correct. 3 Α. 4 Including, I should say, two - that is, the last one 5 Q. 6 for well 3 and the only one for well 6.5 that were after the event, that is, after the event of 6 May? 7 Yes, yes. Yes, that's right, 22:30 would have been 8 Α. 9 afterwards. 10 So that figure for well 3 of 0.25, that was picked up Q. 11 12 by the operator? 13 Α. It appears so from this table. 14 15 Q. But the others were not? 16 Α. That's correct. 17 Then with respect to wells 7.5, 8, 8.5, 9 and 9.5, 18 Q. 19 there were detections for ethylene as well, although the last two were samples taken after the ignition on 6 May? 20 That's correct. 21 Α. 22 In fact, the one for well 9 was taken only about 23 Q. 8 minutes after the ignition, if we assume it occurred at 24 25 about 2.57pm? 26 Α. Yes, that sample seems to be taken very closely after 27 the event. 28 And it shows a high Graham's ratio, over 1000 ppm CO 29 Q. and 24 ppm ethylene? 30 31 Α. Yes, that's correct. 32 We were talking before about the frequency with which 33 Q. goaf stream samples were being taken. Starting with the 34 bottom part of the slide first, is that part of a table 35 that you generated showing where you did and did not have 36 37 samples? Yes, that's right. So I've made a table for when the 38 Α. samples were taken from each location but without any of 39 40 the analysis details. 41 Therefore, we do have samples for 4 May - that's the 42 Q. 43 one that was taken at 3.30 in the morning? 44 Α. Yes. 45 46 And we do have one for 5 May that was taken at 3.20 in Q. the morning? 47

A. Yes, that's right. So the way that we've got this data has been exported from the trending software, or also when we've reprocessed it, that will be the time that was put into the instrument for - you know, there's a set-up page, you type in all your sample details like we were looking at before, you put in the time and the date.

7

17

26

34

40

Looking at the deputy report above it, it appears that 8 9 there was some difficulty accessing the goaf stream around this time, which would explain why they weren't taken. 10 That sample on the 5th doesn't correlate with the deputy 11 12 reports in terms of when the samples were being taken. 13 I believe that that sample may be from actually the 4th in the afternoon, and not the 5th in the morning, and it could 14 15 just be a data entry, what do you call it, you know, AM or 16 PM or the wrong date.

Say if you run that sample after midnight, say you 18 19 were running them on the 4th, then you've got past midnight, it's now the 5th and if you've forgotten to go 20 back and select the 4th for the date again, or adjust the 21 22 AM/PM, then it might have been put into the system like 23 that. So I'm not a hundred per cent sure, but I'd suspect that based on those deputy reports that sample from the 5th 24 was actually taken on the 4th. 25

27 So what you did was tried to reconcile the statutory Q. 28 reports that you had with the samples that were taken? 29 I didn't really do that. This was actually pointed Α. out to me by someone else that was actually looking at the 30 31 deputy reports, and then I was made aware of it. Before 32 then, I wasn't aware, and that's why this table in the original report still has the 5th in there. 33

Q. One thing that we should have pointed out is that neither the sample that's marked there as 4 May or this one here that's labelled 5 May, whether it was taken then or on the 4th - neither of those contained any ethylene? A. No.

And if there was ethylene coming out of the goaf, the 41 Q. goaf stream would be the best place to find it? 42 43 You'd expect that. However, I recall before and after Α. 44 the event, I think the methane levels are quite low, like around 1 per cent, 2 per cent, which is what you'd expect 45 46 more from the tailgate goaf stream. It could be that 47 level, but it could also be more rich, like 5, 10, 15, 20

1	or plus per cent methane in the goaf stream. You'd also
2	expect a bit more CO.
3	
4	So in this period before the event, and then after, it
5	would appear that the goaf stream is - or whatever's gone
6	into the goaf stream bag is guite diluted and it's not the
7	same as the goaf streams that were taken earlier on: you
8	know, we were seeing 50 ppm, 30 ppm, 90 ppm. So it makes
9	me suspect that the goaf stream - and because they weren't
10	taken because it was difficult to access maybe the goaf
11	stream was difficult to get a hold of during that period
12	beroum was arrived to get a nord of adding that porrod.
12	O The next slide is the one that we've snoken about
14	already I'll move on Did you export the data into
14	a corrige of graphs so as to make it perhaps a bit more
10	a series of graphs so as to make it perhaps a bit more
10	Mileringible:
17	A. Yes, that's right, because there's a fot of data, so
18	IL MAKES IL EASTER LO VIEW.
19	0 Did you for the reaf stream coloulate the $CO/CO2$
20	Q. Did you, for the goat stream, calculate the CU/CU2
21	
22	A. Yes, that's correct. That circled bit there, that's
23	the time period where there were quite a few samples
24	missing. So from the 5th until the 15th, there was only
25	one or two samples taken. There was one taken on the 10th,
26	which is that dot in the middle of that red circle.
27	
28	You can see before the event, the CO/CO2 ratio is down
29	relatively low compared to where it is post event, but then
30	there's not much data in between.
31	
32	Q. So we've got the CO/CO2 ratio shown on the vertical
33	axis.
34	A. Yes.
35	
36	Q. This peak here, is that associated with the ignition
37	that occurred on 8 June?
38	A. Yes, I think from early June you can see that trending
39	upwards there, so that would - that's consistent with other
40	gas data, for example, the CO make, where there was an
41	obvious increase in activity, oxidation activity.
42	
43	Q. But the peak, before the ignition of the 8th, got to
44	a CO/CO2 ratio of about 0.088 or thereabouts?
45	A. Yes, something like that. It's below 0.1. certainly.
46	
47	Q. But the normal situation according to the TARP was

a CO/CO2 ratio of 0.2? 1 2 Yes, that's right. Α. 3 This is the long form Graham's ratio for the same 4 Q. data, that is, the same data set, the goaf stream? 5 6 Α. Yes. 7 We heard some evidence about Graham's ratio vesterday 8 Q. and understand that it's about measuring the amount of 9 carbon monoxide and comparing that to how much oxygen has 10 been depleted? 11 12 Yes, it's generally used as a measure of intensity of Α. an oxidation. 13 14 So what is "long form"? 15 Q. 16 When the oxygen deficiency is calculated for the Α. Graham's ratio, there's several different ways that you can 17 do it and there's several different sources of the - say, 18 19 for example, if your initial conditions represent fresh air, you could use the theoretical values for fresh air. or 20 you could take the fresh air from the instrument as 21 22 measured, which would represent the long form of the equation. 23 24 25 Some systems, for example the tube bundle system, because it measures air quite frequently, it would have 26 a fresh air point in its cycle, so it might measure the 27 28 fresh air on the surface once every hour or two, or it could measure an intake underground at the same frequency. 29 It has a reference point for what that analyser is actually 30 31 measuring for fresh air, so it might be measuring 20.8 instead of 20.9, so by using that initial measured 32 reference point rather than a theoretical reference point, 33 34 you can get a more precise or more accurate calculation of the Graham's ratio. 35 36 37 With a real-time sensor, you can't do that because the real-time sensor is stuck underground. It's got no fresh 38 air reference. It's just measuring whatever air it is 39 40 being given. So you would have to use a theoretical fresh air. 41 42 43 For the gas chromatograph, because you're often not taking a bag sample from an intake airway and using that to 44 compare against your sample, you would often use 45 46 a theoretical value. Also, the gas chromatograph - it doesn't have a lot of fresh air references, although it 47

does have one with the calibration at the start of the day, so it would be fairly unusual, because it's a very manual process - I wouldn't say it's the norm in the industry at all, but I've gone and used the fresh air reference from the calibration when it is being done to use that value to calculate the oxygen deficiency for the Graham's ratio instead of using a theoretical value.

9 In this case in particular for the goaf stream, it's given elevated values of Graham's ratio post event. 10 From memory, without the long form of the equation, those values 11 12 that are up around 0.8 might have been, you know, 0.3 or something like that, but with the long form of the Graham's 13 ratio in this case, those samples are returning around 14 0.8 - between 0.6 and 0.1 until early June, but then they 15 16 only slightly increase. They don't increase - you know, there's one point there of almost 1.6, which is close to 17 double, but then there's still a lot there that are around 18 19 0.8 or 0.1 or 1.2.

So from what we know happened in June, we can see the Graham's ratio that was associated with that, and then we can also see a similar Graham's ratio back on the 20th, 17th, 15th. There's one on the 10th there that looks particularly high.

27 Q. The 10th of?

8

20 21

22

23

24

25 26

28 Α. 10 May. From memory, that had a very, very low oxygen deficiency, so it was maybe 0.05, so that could be an 29 unreliable result. In fact, a lot of those Graham's ratio 30 31 values do have a low oxygen deficiency, below the threshold However, there are also Graham's ratios in there 32 of 0.3. that have an oxygen deficiency of over 0.3. So it's likely 33 34 that the ones that have - just because a Graham's ratio has an oxygen deficiency below 0.3 doesn't mean that it's 35 It means it's more likely to be unreliable. 36 wrong. But if 37 you've got that many results that close together all from the same spot that are supporting each other, I think in 38 that case that's showing - usually if you had a Graham's 39 40 ratio where you were getting invalid data, it would be like a scattergram, you'd have Graham's ratios - negative ones, 41 you'd have positive 20, you could have 5, 1, 0.1 - all over 42 43 the shop, but these are all around 0.8 to 1. There's a few down lower, but they were fairly consistent. 44 45

46 Q. We know that according to the TARP the normal 47 condition was a Graham's ratio of less than 0.3. What does

the data in the lead-up to the incident on 6 May tell us? 1 2 Well, there's a small increase there. Again, I think Α. there's a data point there that might have been from the 3 4 5th that we know is really the 4th. It looks like it's just above 0.4. From memory, it had a very low oxygen 5 6 deficiency as well, so whether that's really 0.4 or whether it's slightly lower or slightly higher - like I said, it's 7 unreliable at low oxygen deficiencies. But you can see 8 a little bit of a trend there where it's heading upwards 9 from maybe the 2nd, and certainly those ones on the 4th are 10 a bit higher than those ones on the 2nd. 11 12

13 If we go back further, we can see an elevated area 14 around mid-April there, looks like from about the 11th or 15 the 12th till about the 23rd, you've got a bit of an 16 increase in Graham's ratio there. And then you've also got 17 that period back in March there when the longwall started, 18 where there's a few slightly high readings. But they're 19 all lower than what we've seen from this graph post event.

Q. You told us that you used the actual fresh air as opposed to the assumed fresh air, and you've mentioned a scenario where you might have used 20.8 as opposed to 20.7 or 20.9. A. Yes.

25

20

21

22

23

24

26

40

Q. What sort of difference can a change in the oxygen
 percentage that you use in the calculation of 0.1 per cent
 make?

Well, particularly in this case, because they are low 30 Α. oxygen deficiencies, having any extra oxygen deficiency 31 that isn't real can cause the ratio to be underestimated. 32 And in fact - you know, a lot of - when the Graham's ratio 33 34 is calculated, a threshold of 0.3 might not have been - you know, it might have been counted as unreliable, invalid in 35 terms of interpretation. But if you're using the fresh air 36 reference, you can take away more of the variance in 37 results or any artificial extra oxygen deficiency which 38 isn't really there. I've said that twice. 39

41 Can you compare the results for the long form Graham's Q. ratio against a TARP, for example, or should you be using 42 43 the short form or the assumed level of oxygen? 44 Well, ideally you'd use the most accurate and Α. comprehensive version you could, but that's not always 45 46 available, particularly at the mine site. I wouldn't 47 expect an operator to sit there and calculate out a long

1 form of Graham's ratio. And in fact I've done this just as 2 a process in diligence to see if I can determine whether I can identify anything for the purposes of this 3 investigation, so I wouldn't expect that to normally 4 happen. With TARPs as well, there's the issue of 5 6 overcomplicating them and making things too hard for the operators to actually follow it. 7 8 9 We know, though, that the normal condition for Q. Graham's ratio was 0.3 and the level 1 trigger was greater 10 than 0.5. So even on the long form Graham's ratio, the 11 level 1 trigger wasn't reached except for possibly this 12 13 data point here (indicating). The level 1 trigger for Graham's ratio, without the 14 Α. 15 long form, are you saying? 16 Using the long form. 17 Q. Oh, using the long form. The level 1 trigger was at 18 Α. 19 0.3. 20 Was 0.3. 21 Q. 22 Α. So it will be in between that 0.2 and 0.4, so there's 23 quite a few there. 24 25 Sorry, what would go to a level 2 TARP, though, would Q. 26 be above 0.5? Yes, that's right, I don't believe any of them 27 Α. 28 triggered a level 2 TARP. 29 Thank you. Did you do the same exercise with the bag 30 Q. 31 samples that were taken from the tube bundle point at 3-4 cut-through? 32 I applied a - once I'd done those manual calculations 33 Α. 34 and got an idea of what the oxygen to nitrogen ratio was on that gas chromatograph, I was able to apply that to all of 35 the results for other locations, for example, the 36 37 3-4 cut-through, to see what difference it made. 38 I should have asked you this question, just going back 39 Q. 40 to slide 13: what does that slight increase, as you described it, in Graham's ratio prior to the events of 41 6 May tell us about what was happening in the goaf, if 42 43 anything? 44 Well, it is only a slight increase. If you look at Α. the rest of the trend, you know, if you were looking at the 45 46 trend as a whole without knowing that anything was wrong, then you might say, "Well, that just all looks the same." 47

But knowing what's happened, there is a small increase 1 Maybe it's similar to the increase on 11/12 April 2 there. there, where it's gone up a little bit there. 3 But not having the next data point I'd say is fairly significant. 4 Having said that, we don't know whether the next data point 5 6 would have shown anything or not. 7 This is on the morning of the 6th, do you mean? 8 Q. Yes, yes. Well, the 5th, the morning of the 5th, 9 Α. afternoon of the 5th, morning of the 6th. 10 11 12 This graph is labelled "Raw Carbon Monoxide" for the Q. 13 3-4 cut-through point. 14 Α. Yes. 15 16 Q. And it includes on the horizontal axis a time span from mid-March right through until the time of the second 17 event, on 8 June? 18 19 Yes, that's right. Α. 20 We can obviously see a trend upwards in CO in the 21 Q. 22 lead-up to that event? Α. Yes. 23 24 25 But the event with which we're concerned occurred on Q. 26 6 May, here? Α. Yes. 27 28 29 What can you say about this trend here from late April Q. through until the time of the ignition on 6 May? Is there 30 31 anything significant about the trend that we can see there? I'd really say only that it's increasing. That might 32 Α. The magnitude of it isn't necessarily any be significant. 33 34 higher than what's come previous, although during mid April and late March I believe there were some increased levels 35 of oxidation happening there as well. So that's not to say 36 37 that just because that's there, then that level's something to be desired. There is a small increase before that 38 point. 39 40 41 I'd say what's probably more significant is that step change increase afterwards. So you can tell the data after 42 43 the event, those carbon monoxide readings are higher still only 10 ppm, but they're higher than they've been 44 previously, and there's data points there on the 17th and 45 46 20th of May, which is quite a number of days after the 47 event.

1 2 A person looking at that data prior to the event of Q. 6 May would not have looked at it and seen that there was 3 4 any cause for alarm? 5 Α. Yes, not likely. 6 Does it, though, offer us any insight into what was 7 Q. actually going on? 8 9 I think in hindsight you're able to look for these Α. sorts of things, so, you know, a small increase beforehand 10 might mean something. It might not. I suppose if you 11 correlate the events, then - like I said, yes, the 12 13 increases beforehand - afterwards are more significant, but if nothing had gone wrong and you didn't know that anything 14 was wrong, then that all kind of just looks like a bunch of 15 16 lines going up and down and there's nothing sticking out that far. 17 18 19 Let's go to the next slide, then, which is the Q. calculation of the CO/CO2 ratio? 20 21 Α. Yes. 22 23 Q. The title of the slide says "ratio as measured". Do you mean as measured at the mine, or was that your 24 calculation? 25 26 That's the CO/CO2 ratio based on the raw values that Α. I - you know, if you're going to do a CO/CO2 ratio, that's 27 what you'd use. So I assume that's what was available to 28 the mine. 29 30 31 Again, we see a fairly significant increase before the Q. events of June. But going back to 2 May, or commencing on 32 about 2 May, is there anything about what we see there that 33 34 is of interest in trying to work out what happened on the 35 6th? Well, the CO/CO2 ratio is increasing there. 36 Α. On that -37 that's an outdated graph. That first really high point, I think that's on 5 May, but that's not quite correct. 38 I've reviewed that in one of my graphs in the addendum, 39 where that point is more in line with the one after it. 40 41 So it should be down here (indicating)? 42 Q. 43 Α. Yes, yes, somewhere around there. But even at that point, you can see that's at a similar level to what was 44 going on in mid-April, and when you look at that graph, 45 46 it's a bit of a step change up from what we were seeing for the previous week or two. And then at the time of the 47

ignition and afterwards, there's an even higher change 1 2 there, which persists. 3 4 Q. Focusing on the period leading up to 6 May, what does that data suggest about what was happening in the goaf, if 5 6 anything? It might indicate some increased oxidation activity. 7 Α. CO/CO2 going upwards would indicate that there's extra CO 8 being produced compared to the amount of CO2, which could 9 indicate a high temperature. 10 11 12 You then did an adjusted CO/CO2 ratio? Q. 13 Α. Yes. What the adjusted ratio has done, or what it's doing - it makes the results look a bit more amplified, and 14 the reason for that is because it's taken out the influence 15 16 of the seamqas. CO/CO2 is supposed to be based on the amount of carbon monoxide and carbon dioxide being 17 generated from the oxidation itself, but when we've got 18 19 a large goaf with a lot of seamgas in it and you have carbon dioxide as part of that seamgas, then that can 20 influence that equation. 21 22 So I've taken a number for the ratio of carbon dioxide 23 Now, that's quite difficult, because if you 24 to methane. 25 look in the goaf, at all different places, there's So I've taken the lowest CO/CO2 26 different CO/CO2 ratios. ratio I can find, for the purposes of being conservative 27 with the calculation, and applied that to the carbon 28 dioxide readings to make them a little bit more - what's 29 the word? - consistent with trying to compare that to 30 31 textbook values, which wouldn't compare the - which wouldn't take into account the seamgas associated with the 32 result. 33 34 So looking at that adjusted data, what does that say 35 Q. about what was happening in the goaf? 36 37 There is certainly a step change at the time of the Α. ignition, but also those samples that jump up on the 5th 38 and the 6th there - so I suppose a significant thing about 39 this graph here is because it's from the tailgate and there 40 are samples every day from the tailgate, that maybe 41 provides some information extra to those goaf streams that 42 43 were missing. Because we don't have the goaf stream samples, so we can't use that, so using the tailgate data, 44 we can see that there is an increase there. 45 46 47 Q. An increase in what?

An increase in the CO/CO2 ratio, which would indicate 1 Α. 2 an increase in oxidation. In terms of comparison to June, Having said that, that could be related to the 3 it's small. 4 size of the heating as well, because even though I've done a seamgas adjustment for this, that hasn't taken in all the 5 6 seamgas into account, because it's a conservative 7 measurement, and the remaining seamgas is still going to dilute the rest of the sample. So it would make sense that 8 if the size of a heating increased, it might be apparent as 9 that dilution factor becomes less with the seamgas. 10 11 12 Q. You also looked at the data from the goaf seals? 13 Α. Yes, yes. 14 15 We can proceed through that reasonably quickly, Q. The data points were quite widely spaced in time? 16 I think. Yes, that's right. I think it could be one or two 17 Α. weeks between some of the samples, so those lines on those 18 19 graphs don't necessarily mean - it probably would have been better represented with just dots instead of lines, but 20 that's what I've done. 21 22 23 We can see 39-40 cut-through on this one. You can see the oxygen there is around 20 per cent until around 24 23 April, and then it drops off, and there's 25 a corresponding increase in nitrogen, above 80 per cent, 26 which would indicate the use of inertisation, because 27 28 there's 78 per cent nitrogen in air, so anything over 80 per cent has obviously got to be a dilution of a more 29 concentrated source, which would have to be the Floxal, or, 30 31 sorry, would have to be nitrogen. 32 So it's consistent, or generally consistent, with 33 Q. 34 fresh air, or at least the oxygen levels are, until that 35 point? I wouldn't call it fresh air, because there's some 36 Α. 37 methane in there. But if we look at that red line for the oxygen there, that's somewhere around 20, so that looks 38 like it's above 15 and below 21 for most of the part, so 39 that's a relatively high amount of - or a relatively low -40 the predominant portion of that sample is air, yes. 41 42 43 Q. We also have the raw carbon monoxide for the same 44 spot? 45 At this location, you can see the carbon Α. Yes. 46 monoxide is around 50 ppm. That scale is in percentage on But it's at about 45, 50 ppm around the 47 the side there.

TRA.500.019.0031

1 beginning of April, and then it drops off particularly on the 23rd, which might be associated with the nitrogen, but 2 it looked like it was dropping before that. 3 4 5 Q. If we go back, it does look as though, if there was 6 inertisation, it commenced on or about 23 April? 7 Α. Yes. 8 9 So those coincide. Can we then go to the graphs for Q. 38 cut-through, and this is slide 21. Again we see an 10 inverse relationship between nitrogen and oxygen. Does 11 12 that suggest inertisation? 13 Α. Yes, from the 23rd or 24th - I can't tell from the 14 scale there what day exactly, but you can see that the oxygen, it is dropping down to - from looking at that 15 16 graph, I can't remember exactly - it looks like about 15 per cent, maybe lower, and then it's dropped a lot 17 lower, with the influence of nitrogen apparent by the 18 19 concentration being above 80 and probably about 90, by the 20 look of it. 21 22 Q. The raw carbon monoxide data tells a similar story in terms of it dropping at about the same date, 23 April? 23 Note that the carbon monoxide from this sample 24 Α. Yes. 25 is over 150 ppm on 20 April. They were those samples we were looking at in the table before, probably also 26 associated with that ethylene that we saw, the high levels 27 of CO, up to 150 or 190, whatever they were. 28 29 Just two more slides before I'll suggest that we break 30 Q. 31 for morning tea, if that's convenient. Can we look at B1 cut-through. A similar story told here. There appears 32 to have been an increase in the amount of nitrogen from 33 34 about 23 April and a corresponding drop in oxygen? Yes, that's right. 35 Α. 36 37 The dates don't completely line up, but what appears Q. to be a corresponding decrease in carbon monoxide at about 38 the time the nitrogen increases? 39 Yes, and also note the highest carbon monoxide there, 40 Α. around 60 ppm, is around 17 or 18, 19 April, something like 41 that, around mid-April. 42 43 I'm now going to move to the goaf wells, so 44 MR HUNTER: I wonder if that's a convenient time. 45 46 47 THE CHAIRPERSON: Yes. We will adjourn until 11.45.

1	Thank you.
2 3	SHORT ADJOURNMENT
4	
5	MR HUNTER: Q. There's one matter in connection with
6	slide 16 that I forgot to mention, and I'll just go back to
7	that. It concerns the scale on the vertical axis. There
8	appears to be a repetition of the same number. Is that
9	because the three digits that were supposed to be there in
10	every second one didn't show up?
11	A. Yes, that's just displaying the amount of decimal
12	points on the scale, so that would be in 0.005 increments
13	rather than 0.01 repeated twice.
14	
15	Q. So it should be 0.01, then 0.015 then 0.02, et cetera?
16	A. Yes.
17	
18	Q. You looked at the data that was reported from the
19	monitoring equipment that was fitted to each of the goaf
20	skids?
21	A. Yes, that's right. The goat skids, most of them
22	appear to have four gas sensors or at least are measuring
23	rour gases - carbon monoxide, carbon dioxide, methane and
24	particularly considering the goaf stream didn't look like
20	it had a lot of even methane in it or carbon monoxide
20	before and after the event. So all of the goaf wells have
28	been analysed from their raw data that comes out of the
29	Citect system. I've graphed it up from the time period
30	from either the start of the longwall or when the goaf well
31	was commissioned or taking any data.
32	
33	Q. You also did reprocessing of that data. What did you
34	do in terms of reprocessing?
35	A. I wouldn't call it reprocessing, maybe more so trying
36	to correct the data in terms of - you know, these are
37	real-time sensors that are on a goaf skid probably subject
38	to difficult environmental conditions in terms of humidity
39	and temperature and that sort of thing. Some of the
40	readings on the goaf skids don't seem to - if there's been
41	a hand-held reading that correlates with it, they might not
42	be the same, or the GC data isn't the same.
43	
44	So I've attempted to determine when a sensor is
45	reading incorrectly where it's significant and then apply
46	a response factor to that gas to try and get what the real
4/	uata should have been out.

TRA.500.019.0033

1 2 For example, if a carbon monoxide sensor was reading twice as much as it should have, then I've compared that to 3 4 the GC results, done my best to estimate by what factor it was overestimating and then applied that factor to the raw 5 data so that you get a more representative or accurate 6 7 measurement of those gases. 8 9 And also, in an attempt to try and get a more meaningful Graham's ratio out of some of those gas wells, 10 in the end I don't think that was very successful, because 11 of the variation in the - well, I suppose the gas well 12 sensors aren't accurate enough to get absolute values of 13 Graham's ratio that are particularly reliable, because any 14 15 small measurement error in any of the sensors could affect the overall nitrogen, or the nitrogen calculated, which 16 could then affect the entire result. So I did attempt to 17 do some Graham's ratios from the goaf wells with the raw 18 19 data and the corrected data. 20 Can we start with a well that was labelled GR04M001.5. 21 Q. 22 It's a side-on view, but do you recognise that as being 23 a view from the top down --24 Α. Yes. 25 26 -- a plan of the longwall 104 showing the locations of Q. all the vertical wells along here? 27 28 Α. Yes. 29 Adjacent to the tailgate, but also that well 30 Q. 31 GR04M001.5? Yes, that's close to the face there, and then there's Α. 32 also M001 on the maingate side, and then up the back 33 34 there's a few goaf wells as well. 35 This is a graph showing the CO from that well MO01.5 36 Q. 37 from 2 May through until the day after the incident. Yes, that's right. For the most part, the CO looks 38 Α. like it's undetectable in terms of the sensors either 39 40 reading a quarter of a part, or maybe that might be the baseline for zero for that detector. The only time it 41 seems to detect anything, and it's only up to about 2 ppm, 42 43 is on the day of the 6th, which appears to be on the morning of the 6th, and then the reading goes back down to 44 45 reading baseline or zero. 46 47 Q. So it's only a very small bump, if I can call it that,

© Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

but what, if anything, does it suggest, particularly 1 2 looking back on what we know now, about what was going on? Well, it's certainly interesting that that small 3 Α. amount is detected on that day and not on another day, or 4 it's not on the 2nd or the 3rd or the 4th or the 5th, but 5 6 it is on the 6th, so that could be for a reason, or it could be coincidence. 7 8 9 If it's for a reason, what reason could there be for Q. an increase in the amount of carbon monoxide reporting to 10 that well close to the face on the morning of 6 May? 11 12 Well, carbon monoxide is an indicator of spontaneous Α. 13 combustion. At those low levels, you'd expect that all throughout the goaf at only 2 ppm, but because it's reading 14 zero the whole time, and then all of a sudden it sees 15 16 something well over what it has been seeing and then it 17 goes away, that might indicate that there was some oxidation activity or something's happened that's caused it 18 at that time to be able to detect something. 19 20 Go forward, then, to vertical well number 3. Do we 21 Q. 22 have there the carbon monoxide that was reporting to that well? 23 Yes, that's right. 24 Α. 25 26 Q. We can put I think to one side this data here (indicating), but I'm more interested in this peak here 27 28 (indicating), which shows about 160 parts per million on or about - I think the date on the X axis is about 22 April. 29 Yes. 30 Α. 31 That's associated with a sharp rise from about 20 to 32 Q. 40 parts per million up to just short of 160? 33 34 Α. Yes. I'm just trying to find the picture in my report for it because I think it's important to compare the flow 35 to the readings. I'm on page 19 of my addendum 2. 36 It 37 looks like the CO was increasing until the 17th or 18th, And and then it appears the flow was reduced on that well. 38 then when the well was turned back on, that's when we see 39 40 that really high CO reading - when I say "really high", it's higher than anything it's seen before, at close to 41 160. 42 43 44 So could that be explained simply by an accumulation Q. of carbon monoxide at the base of that well whilst it was 45 46 turned off? 47 Well, if you look at the dates, the carbon dioxide Α.

1	initially seems to drop off
3 4 5 6 7 8 9 10 11 12 13	Q. Sorry, carbon dioxide? A. Sorry, carbon monoxide. It drops down, but it's not an instant drop as if it had just accumulated in the well and then been evacuated. It seems like it comes - that level reduces over some time. It's hard to say. I'm not an expert on how - you know, the volumes and the flows of the wells and how they start up and stop and that sort of thing. But I suppose there's no flow between the 18th and the 22nd, so there's potentially - you know, that data there is not necessarily representative of what would have been detected if there was a flow.
14 15 16 17 18 19 20 21 22	Q. Go to well 4.5. Here I'm interested in what's happening on or around 17 or 18 April. A. Yes, so that scale there - it's a bigger scale. So around 17 or 18 April, that is around 140 ppm, by the look of it. You can see on those two particular days the readings there do seem significantly higher than the readings prior to that.
22 23 24 25 26	Q. Go now to well 6.5, which is closer to the face. This is CO from 8 to 25 April. A. Yes.
20 27 28 29 30 31 32	Q. What can we see on this graph? A. Around the - I guess from perhaps 11 April we can see a bit of an increase in CO, up to 100 ppm. Then it would appear that the CO drops off. I'm just having a look at the flow again. It looks like it's steady until the 14th.
33 34 35 36 37 38 39 40 41	Q. Sorry, say that again? A. I was just looking at the flow. It appears that the flow continues until 14 April, and the CO drops off before then, but then the flow appears to restart or is intermittently higher than previous, from the 17th to the 18th, so it looks like there was some flow for a short amount of time in that period where those higher CO levels have been detected, and then the flow has been turned off again from the 18th until the 22nd.
42 43 44 45	Q. The levels reached, what, just short of 180 parts per million? A. Yes, that's right.
40 47	Q. Did you do a methane free calculation for carbon

monoxide on this well? 1 2 Yes, I did. Α. 3 Does this slide, slide 35, show the graph that 4 Q. reflects those calculations? 5 6 Yes, that's right. The reason I've graphed the Α. methane free is because these are goaf wells - I assume 7 they're designed to remove methane from the mine, so they 8 will have a significant amount of methane in them, and you 9 10 could consider that the methane dilutes the oxidising portion - or the portion of the sample that may represent 11 12 the oxidation activity, because methane - oxidation occurs 13 in oxygen. It doesn't occur in methane. So if you have more methane, that, by a percentage in concentration volume 14 perspective, may drop the amount of CO, which doesn't 15 16 necessarily mean the CO has dropped or risen; it could be that the methane has diluted it less or more. 17 So I've used this methane free calculation to try to remove the effects 18 19 of dilution from the methane when interpreting these carbon monoxide readings. 20 21 22 Q. So varying levels of methane will affect the apparent 23 level of carbon monoxide? Yes, that's right. 24 Α. 25 26 Q. And removing methane from the equation enables you to get a much better idea about what's happening in terms of 27 28 carbon monoxide? 29 Yes, and that's with the assumption that the carbon Α. monoxide is not associated with the methane and is more 30 31 associated with the oxygen or air or remaining goaf gas portion of it. 32 33 34 Q. Does it show, though, really an amplified version of what we saw in the preceding slide? 35 Yes, it shows the same trend, it's just a different 36 Α. 37 scale. It's a bigger number. 38 39 So when we see a number there such as that peak, which Q. is probably, what, about 325 parts per million, is that 40 parts per million in absolute terms or is it only parts per 41 million of whatever was left after you took the methane 42 43 out? 44 That's parts per million in terms of - you know, that Α. number has been multiplied up by a factor depending on the 45 46 amount of methane that was in the sample. To correlate that exactly with raw readings is, I'd say, difficult, but 47
1 it's a relative number still. 2 3 Q. Did you also calculate the Graham's ratio for this 4 well? Yes, that's right. Having said that, like I said 5 Α. before, even though I've tried to do my best to get the 6 7 most representative Graham's ratio, I've found that with the wells it is very difficult because there are so many 8 9 different sensors involved that can affect the readings. So even where I've corrected it, I'm not a hundred per cent 10 sure myself that that is the true reading. 11 12 13 On top of that, in the wells, where there's methane, you would also expect there to be goaf gases, for example, 14 air that's already reacted with coal, and not necessarily 15 16 at a higher temperature, but at normal temperature, which would increase the amount of nitrogen, which would in turn 17 increase the oxygen deficiency. So in general I'd say the 18 19 goaf wells, you're more likely to get a much underestimated Graham's ratio. 20 21 22 Q. Whatever the limitations are of the Graham's ratio, in terms of analysing the trend, are there limitations of the 23 methane free CO exercise that you did? 24 Well, let's say if you had 99 per cent methane and you 25 Α. had 1 ppm of CO and then you removed 99 per cent of that 26 methane and had to multiply that 1 by 100, you'd have 100. 27 But if it was reading 1 instead of 2, then you'd have 200. 28 So if you've got really high levels of methane and low 29 levels of CO, you could kind of - the level of accuracy at 30 31 those low levels would potentially distort the methane And it's similar with air free. If you've got 32 free. a sample that's mostly air and a very low CO value, you 33 34 could distort that final reading. 35 So I'd say the methane free would probably work better 36 37 at methane levels that are, say, less than 80 per cent or have reasonable amounts of CO. It's hard to put -38 I haven't looked at this in enough detail to figure out the 39 40 exact thresholds that that would work and that it wouldn't, but I'd imagine that would be something to look at. 41 42 43 Q. What confidence, if any, or comfort, if any, can be taken from a general or a rough correlation between the 44 peaks in the raw CO data and the methane free? 45 46 Α. I suppose that it shows that the reason the methane 47 was lower before wasn't just because there was extra

1 methane diluting it or something. It puts that trend into perspective, so we can take the dilution factor out of it, 2 so we can see that there is an increase in CO at that 3 location with or without the methane involved. 4 5 6 So does that suggest an increase in oxidation Q. 7 activity? Yes, ves. 8 Α. 9 10 Q. Just so it's clear, you understand that this period we're talking about was a period that was associated with 11 a PUR campaign on the longwall face? 12 13 Α. Yes, or a period after. 14 15 Q. Let's go to well 7. This is the raw CO data? 16 Α. Yes. 17 We see a similar peak around 17 to 19 April? 18 Q. 19 Yes, that's right, and we've seen those previous Α. couple of gas wells that show the same pattern there, with 20 the increasing CO around the 17th, 18th, 19th. And also 21 22 with the flow stopping, it looks like there was a gap in 23 that data. That could be because the flow stopped. I'd I think there's have to look at the flow graph here. 24 some - I've identified some issues here with the flow 25 reading on the skids, so it doesn't seem to match up with 26 what the sensors said compared to what I've seen in the 27 28 notes that were taken. But all the same, from that data you can see there's a higher CO reading around 18/19 April, 29 which is consistent with the location beforehand and the 30 31 one before that. So we've got three gas wells that are 32 showing the same sort of trend. 33 34 Going forward, then, to 4 May, do we see a similar Q. trend upwards in the amount of CO? 35 Yes, that's right, from the 4th onwards we can see an 36 Α. 37 increase compared to the level previous there, over the previous couple of weeks. 38 39 40 Q. You did a methane free CO calculation with that data, which led to what we can see here in slide 39? 41 Yes. Α. 42 43 44 But it shows generally the same trend? Q. Yes, that's right. It shows a similar trend here. 45 Α. 46 Where the trend is fairly similar, it's probably because there is a fairly consistent level of methane there, so 47

.18/03/2021 (19) 1758 S W MULLER (Mr Hunter) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 there's not a lot changing with the methane free. 2 This is slide 40, the Graham's ratio from the same 3 Q. Accepting the limitations you've described, does the 4 data. Graham's ratio correspond to the spikes in CO that we've 5 identified in the previous two slides? 6 7 Α. Yes, we can see around the 17th, 18th, 19th of April there we've got some increases in Graham's ratio. 8 Thev seem to be fairly sharp, short. Could be because the well 9 was shut in at that time. And then again at the beginning 10 of May we can see an increase in Graham's ratio there. 11 12 13 Getting the absolute or the most accurate Graham's ratio from a well is very difficult. Getting a trend is 14 a bit easier. It still has some issues, but we can see 15 that those two coincide with the increased CO. 16 17 You undertook a GC response corrected Graham's ratio. 18 Q. 19 What do you mean here? What I would have done here is compared the oxygen, 20 Α. methane, carbon dioxide, carbon monoxide from the GC bags 21 to the skid response or the sensor response from the gas 22 skids and multiplied that by a factor which makes it more -23 which makes it match the GC data. So in this case - and it 24 shows the same thing without having done that, anyway. 25 26 There's an increase in Graham's ratio around the 5th. 27 28 Q. So does that suggest an increase in oxidation 29 activity? Yes, yes. 30 Α. 31 There's also a temperature measurement on these skids. 32 Q. Was this well, well 7, interesting in the sense that it 33 34 showed a spike in temperature commencing on about 4 May? I'm not that familiar - or I'm not familiar at 35 Yes. Α. all with temperature sensors on gas skids. You can see 36 37 that graph, you know, it's got bits that stick out of it and bits that drop off, but it looks to me like that 38 trend's gradually going downwards over time. I'm not sure 39 whether that's because the sensor's just drifting or 40 whether it's because it's April and it's getting colder, 41 but around the 5th you can see there's a bit of an increase 42 43 there, which doesn't seem to follow that trend of gradually 44 going downwards. I mean, there is that drop-off beforehand, so that makes it difficult to get a smooth 45 46 trend, but that does seem to stick out of trend a little. 47

1 Q. The next well closer to the face is well 7.5. Did you 2 graph the oxygen that was being pulled out of the goaf on this well and also the methane? 3 4 Α. Yes, that's right. You can see the oxygen there. The first grid line is 10 per cent. Most of that oxygen from 5 the 20th onwards is above 10 per cent, so I think it looks 6 like it's between, say, 14 and 12 per cent for most of the 7 part there, the oxygen. 8 9 We can see the fluctuation in the amount of methane. 10 Q. Does this graph perhaps highlight the potential 11 12 significance of doing a methane free calculation when 13 you're looking for a trend in CO? Oh, this graph not so much, because if you look at the 14 Α. methane, from about the 20th onwards it's between 30 and 15 16 40 per cent, so a methane free is not going to really make much difference there. But say if the methane was around 17 30 or 40 per cent and then all of a sudden it jumps up to 18 19 70 or 80 per cent, then that would have more of an influence on the methane free. But, yes, certainly those 20 increases and decreases in methane is what the methane free 21 22 would take into account. 23 Let's go to the next slide, slide 45. Does this show 24 Q. the carbon monoxide from the real-time data? 25 26 Α. Yes, that's right. 27 28 Q. It shows that the well was shut in from just before 29 2 May? Yes, that's correct. I'm not sure what those spikes 30 Α. 31 in the readings are around the 26th. It could just be maintenance tasks, or that second spike coincides with the 32 skid - you know, that data returning, so it could just be 33 34 the skid's been turned on and that's what happens. 35 Did you calculate Graham's ratio for this well? 36 Q. 37 Yes. The reason I've tried to adjust the Graham's Α. ratio, or the gas readings to get a Graham's ratio from 38 this well is because from the original data, I recall it 39 40 was Graham's ratios that were going between negative numbers and, like, Graham's ratio of 2 or something, so it 41 was not making any sense at all. 42 43 44 So I've corrected the response. I don't know how much difference that's made, but what seemed to make a really 45 46 big difference is removing the samples between 8 in the morning and 9 o'clock at night. For some reason, that's 47

.18/03/2021 (19) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 when the response was going really strange. So I could quess that that may have had something to do with the 2 Maybe during the day something happens with 3 temperature. 4 the sun shining on a sensor or something, and it gives a bad result or an inconsistent result. But, still, 5 6 whether or not those absolute numbers for that mean a lot 7 is not clear. 8 9 In any event, it had been shut in by some time on Q. 2 Mav? 10 Yes. Α. 11 12 13 Q. Let's go to well 8. Does this show the methane and 14 oxygen? 15 Yes, this is the methane and oxygen on skid number 8. Α. 16 You can see from about 27 April onwards the oxygen seems to be around 10 per cent, thereabouts, and the skid has been 17 shut in around 3 May, by the looks of it. The flow should 18 19 reflect that. Then it was turned back on on the same day, and the oxygen's still around 10 per cent. And then - you 20 can't see it from this graph, but it was shut in again on 21 22 the 4th, but it continues to receive gas readings. It 23 appears that the sensors are still measuring whatever gas is coming out of that well, even though it might not be on 24 venturi any more. 25 26 So it might have been free venting, do you mean? 27 Q. 28 Α. Yes, I suspect. 29 Q. Just looking at the 6th, we can see on the 6th that 30 31 there's a concurrent dip in methane and oxygen. Is that consistent with both of those gases being consumed in what 32 occurred in the incident? 33 34 Α. Oh, I haven't looked at those particular readings in enough detail to comment on that as a really zoomed-out 35 view, kind of, as well. 36 37 Let's go to the carbon monoxide. Did you undertake 38 Q. the corrected carbon monoxide exercise? 39 Yes, I did. This graph - actually, there's also an 40 Α. 41 updated version of this in my addendum 2. This was originally done with only GC readings. I couldn't tell 42 43 exactly where the corrected values should start from. In my more recent version, when I've had access to the 44 hand-held readings that were associated with this, I was 45 46 able to get a more accurate indication of that. But either 47 way, the graph doesn't look that much different.

1 2 On the original graph, the CO was really high between the 1st and the 6th of May, and when I compared that to the 3 GC results and the hand-held, it seemed that the CO was 4 being overestimated at this point, so I've made sure to try 5 6 and get a more accurate concentration that that should have 7 been measured at. 8 9 We can see, though, a trend on the 6th upwards in Q. terms of CO. Is that same trend replicated on the more 10 recent graph that you did? 11 12 Yes, it's all the same. It doesn't make a lot of Α. 13 difference visually when you're looking at it like that as to the absolute numbers. 14 15 16 Q. Let's have a look at that, then. You've marked on this slide, slide 50, 3pm? 17 Yes. You can see there's a steady but - you know, it 18 Α. 19 looks like an exponential increase around 6 May prior to the ignition at this location, which may be significant to 20 try and determine what happened. 21 22 23 Q. What does that rise or that trend upwards suggest was 24 going on? It certainly suggests that more carbon monoxide was 25 Α. 26 reporting to this sensor on the morning or the day of 6 May. And in fact that - because this goaf well appears 27 28 to be free venting and not sucking the gas out at its normal rate, this increase continues until actually after 29 the time of the event, so it's - I'm not the best person to 30 do the calculations on how long it would take the gas to 31 get from the bottom of the well to the top of the well, but 32 it could be half an hour or an hour, something like that. 33 34 I think Martin might have referenced something in his That's an increase in CO and potentially an 35 report. increase in oxidation activity reporting to that location 36 37 on that day. 38 Did you do a graph that shows a more granular look at 39 Q. 40 that data? 41 Yes, that's right. That shows that in the two days Α. prior, at least - we've got a little bump on the 5th there 42 43 just after the PM, but there's not a lot of other data that 44 looks like it's doing the same kind of exponential increase 45 in that sort of shape earlier on on those two days, and 46 before that, as well. That seems to stand out as being different from the rest of the data. 47

.18/03/2021 (19) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 2 Q. But again we can see more clearly the upwards trend on the morning of the 6th? 3 4 Α. Yes. 5 6 Let's go to well 8.5. You've included in this series Q. 7 the flow graph for that well? Α. Yes. 8 9 10 Q. So you can see periods when it was flowing at a touch under 800 litres a second, but also periods when it was in 11 12 the vicinity of 1000? 13 Α. Yes, that's what it appears. 14 15 Q. Dropping back down to somewhere around the 600 mark? Yes, that's right. 16 Α. 17 Leading up to the time of the incident? 18 Q. 19 Just to point out as well, I'm not an expert on goaf Α. well flows, but this data came with the gas data, so that's 20 why I've trended it. 21 22 23 Q. This is the methane and the oxygen? The oxygen at this well is similar to wells 24 Yes. Α. numbered 8 and 7, 7.5, where that oxygen is around 25 10 per cent, looks like from about 28 April to 4 May. 26 When the flows are reduced, that correlates with a reduction in 27 28 oxygen and an increase in methane. 29 If we go to the next slide, slide 55, is this the 30 Q. methane free carbon monoxide calculation at that well 31 showing a trend upwards commencing on 4 May? 32 Yes, that's correct. The raw data looks like it's 33 Α. 34 increasing slightly, but when you apply the methane free calculation, there's a bit more of a step change involved, 35 and there is that increase in methane that we saw with the 36 37 reduction in flow on the skid, but there's an increase in carbon monoxide if you take that into account. 38 39 40 Q. Perhaps for what it's worth, you did calculate Graham's ratio? 41 It seems to be increasing. There's all these 42 Yes. Α. 43 little bumps sticking out at strange times. That's likely 44 to be associated with one of the sensors drifting at maybe 45 certain times of the day or something. I'm not sure 46 exactly how to explain that, but the trend seems to go up, not very much, but gradually from the 1st until the 3rd and 47

then it drops off a bit after the 4th, and I'd say that's 1 likely to be associated with the extra methane. 2 There's probably also extra nitrogen or oxygen depleted goaf gases 3 4 that will be part of that, which would increase the oxygen deficiency and drop the Graham's ratio. 5 6 7 Q. Let's go to well 9. Again, the first slide, which is slide 58, shows the amount of flow, peaking on about 3 May 8 somewhere north of 1400 litres a second? 9 Yes. 10 Α. 11 12 If we go to the next slide, we can see methane and Q. 13 oxygen? Yes, that's right. I suppose you can see the methane 14 Α. 15 dropping gradually over time there and you can see the 16 oxygen slowly increasing. Could you take me back to the flow, please? There was an increase in flow on the 3rd and 17 the 4th. We'll just see how that correlates with the 18 19 oxygen and methane on the next slide, please. So we can see that increase in flow between the 3rd and the 4th 20 there, there's a drop in methane, a little bit more of an 21 22 increase in oxygen, and then when it returns to what it 23 was, you see more methane and less oxygen. 24 25 Let's go to carbon monoxide. This is the raw data? Q. Yes, that's the raw data. I didn't do any GC 26 Α. adjustments on this one, because there were no bag samples 27 28 taken before the event, and after the event that sensor was exposed to very high levels of carbon monoxide, which makes 29 me doubt the integrity of that sensor from there after, 30 because they can get, I guess, exhausted, or poisoned might 31 be a word with the sensors, when they're exposed to high 32 levels for a prolonged period of time. 33 34 35 Just looking at the raw data, though, we see a general Q. upward trend in the amount of CO from about 30 parts per 36 37 million up to about 90 at the time of the event or shortly before? 38 Yes, that's right. 39 Α. 40 41 What does that suggest? Q. We've seen on a lot of the other goaf wells that from 42 Α. 43 when they're turned on, there is a bit of an increase in 44 CO, and then once the longwall moves past, maybe it drops 45 off again. In this case, I mean, it is increasing, and 46 there's also those extra spikes in that period between the 4th and the 6th that looks like a little bit more variation 47

.18/03/2021 (19) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 of gas readings as compared to how the sensor was 2 responding previous to that. 3 4 Q. But if you take out the methane, which is what you did in this graph, it looks rather different? 5 6 Yes, it looks like there is a step change there when Α. the methane's taken into account. 7 8 9 So is that something that we can see from about this Q. point here, the 4th? 10 Yes, that looks like an increase in CO and likely an Α. 11 increase in oxidation activity from the 4th. 12 13 The next slide, you've marked on it the timing of the 14 Q. event with the red vertical line but also the point in time 15 16 at which the skid on well 8 was turned off? Yes. Yes, this graph was actually from one of my 17 Α. first drafts, and I was trying to look for a reason why 18 19 there would be some sort of change after that point, and not being aware of everything that was occurring, that had 20 occurred, around that time, there was that skid number 8 21 22 that was turned off - that might explain why there was more methane there, although it was associated with a drop in 23 flow on that skid as well. But either way, when the 24 25 methane free is done, there is a step change in the CO. 26 Again, you did do the exercise of calculating Graham's 27 Q. ratio? 28 29 The Graham's ratio seems to be increasing from Α. Yes. the start of May, gradually, and then it - you can see on 30 31 the 4th there, there's a few spikes which seem a little bit out of the ordinary, and then it seems to maybe plateau out 32 a bit and not continue with that increasing trend. 33 But 34 again that could be associated with the extra methane. which may be associated with excess nitrogen, which may 35 explain why the Graham's ratio is staying the same there, 36 37 or not increasing. 38 We know that there was, perhaps fortuitously, a bag 39 Q. sample taken from this goaf well a matter of about 40 8 minutes after the ignition? 41 Α. Yes. 42 43 44 If we look at this slide, slide 64, we can see that Q. 45 someone took this sample? 46 Yes, that's correct, someone's taken this sample from Α. 47 the goaf well at, what is it, 5 past 3 or something around

that time. CO readings from the real-time and the skid 1 show CO levels that would indicate that the sensor's been 2 maxed out at that particular time. The hand-held monitors 3 4 might have a limit of response, or real-time sensors in general, I should say, which could be 500 ppm or 1000 ppm 5 6 depending on the model, and some might give a reading that says "over range", which might explain why that one says 7 "high", because they don't have a number to associate with 8 9 it. 10 Q. The GC analysis of it, though, showed significant 11 amounts of carbon monoxide in excess of that which had been 12 13 read by the hand-held? Yes, that's right, the GC showed around 1000 parts per 14 Α. million of carbon monoxide; from memory, around 500 parts 15 16 of hydrogen; the ethylene there, off the top of my head, maybe it was 20 parts - I've got it in my report; and then 17 what we can see there to the right of the ethane is an 18 19 acetylene peak. 20 What's the significance of acetylene? 21 Q. 22 Α. Acetylene occurs at temperatures higher than ethylene. 23 Probably closer towards 200 that would begin to appear. But if that's 20 parts of ethylene, that's a significant 24 amount of acetylene to go with it. That's, I'd say, an 25 indication of coal combustion or some sort of combustion 26 process or like. 27 28 The next graph just shows the GC data. 29 There's only Q. a small number of data points, but it shows here the carbon 30 31 monoxide in excess of 1000 parts per million? Yes, that's right, 1000 parts. 32 Α. 33 34 Q. That's post the event? Yes. Those sorts of readings would indicate some sort 35 Α. of coal combustion. 36 37 I'm going to ask you some more about that in a moment 38 Q. once we look at the data for well 9.5. 39 40 Α. All right. 41 42 Q. So can we do that now. This is well 9.5, which was, 43 we understand, about 25 metres back from the face? 44 Α. Yes. 45 46 Q. The first graph just shows the flow on that well? 47 Α. Yes.

Q. The second shows oxygen and methane?

A. Mmm-hmm.

Q. This is the data from the bag samples, and post event the amount of CO is a bit over 30 parts per million? A. Yes, the CO, that first sample there, is at over 30 parts per million and then it drops down. That may be associated with the majority of the combustion gases produced by the explosion leaving that area, and then the CO appears to be increasing slightly from below 15 up to over 20 over the next few days, and then there's a sample where it's a bit lower, and then it returns to that trend after that.

16 Q. We know that 25 metres back, in well 9, the amount of CO that reported to the well was over 1000 parts per 17 million, whereas this goaf well, 25 metres closer to the 18 19 face, had a dramatically lower amount, just in excess of 30. What does that data tell us about what happened? 20 It tells us that there's a very different atmosphere 21 Α. 22 of gases reporting to those two locations. So the carbon 23 monoxide from the real-time sensor on 9.5 indicates that it goes over range, which would be over 5 per cent for carbon 24 25 dioxide. So there's a lot of carbon dioxide there, but the 26 carbon monoxide is still relatively low, say below 40 ppm. That would indicate an efficient combustion of methane, to 27 28 me, where the majority of the methane has been converted to carbon dioxide, and there's not a lot of carbon monoxide 29 associated with that. 30

In contrast, at hole 9, from the sample taken 5 minutes later, there's a lot of carbon monoxide, at 1000 ppm. We get all the other combustion gases that are associated with that, and it seems interesting to me that those concentrations are so different at two goaf wells that are close together.

39 There is a bit of extra carbon dioxide in the well number 9 as well. It's difficult for me to tell if that 40 carbon dioxide has been produced as either some sort of 41 prior heating or whether it's been a partial dilution of 42 43 the efficient combustion gases from hole number 9. And also there's a potential that that burnt - the higher 44 combustion indicators in hole number 9, whether that has 45 46 come from coal dust being combusted as a result of the explosion or whether it's existed before then and somehow 47

.18/03/2021 (19) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

been - that's not - I can't tell that from the data. 1 2 3 If this is outside your expertise, say so: does it Q. 4 tell us anything about where the combustion process started 5 or the ignition started? 6 Possibly. Like I was saying, it's either been Α. 7 produced there as part of the - it's been produced by the explosion or it was produced associated with the ignition 8 of the explosion. So considering that product is being 9 detected in the goaf and at a gas well further back in the 10 goaf, I'd have to think that that gas was generated in the 11 12 goaf. 13 To move to another topic, did you try to undertake 14 Q. some calculations to see if you could work out, if there 15 16 was a heating of coal, what its size was and what its intensity was? 17 Yes, and that's mostly based on data from post the 18 Α. 19 event. 20 Just so we know what we're looking at, we're looking 21 Q. 22 at slide 71, which is the adjusted CO/CO2 ratio for 3-4 cut-through in the tailgate? 23 Α. Yes. 24 25 26 Q. Is this the same graph as the one we looked at earlier, although without the annotations in red? 27 28 Α. It's the updated version of the graph, where I had a data point that was sticking up earlier than it was for 29 corrected data. But to put this in context, I think it's 30 31 useful to look at the Graham's ratio in the goaf stream from that period beforehand. 32 33 34 Q. I don't think I have that on a slide here at the This is the goaf stream, you said? 35 moment. Yes, it was one of the first slides. 36 Α. 37 Yes, I'm just identifying which one it is. 38 Q. Slide 13. It might be easier for you, Mr Operator, to return to slide 39 40 13, if we could, please. Is that the one we're talking 41 about? Yes, that's right. With the long form Graham's ratio 42 Α. 43 that's been reprocessed post the event we can see Graham's 44 ratio values - between re-entry in May and the second event in June, we can see values around 0.8 and 1. 45 We can see 46 that that ratio does increase in June, and there is one 47 data point where it is 1.6, and that would indicate that

1 during May, and from those earlier samples taken in May, we 2 can see there was an elevated Graham's ratio existing at And that's before the second event - may have 3 that time. 4 become more apparent by the CO make and other things, but then again that's the reprocessed long form that it's 5 6 unlikely the mine would have seen at the time. 7 Should we go back to the CO/CO2 slide? 8 Q. 9 Α. Yes, that would be good. 10 Could we go back to slide 71, please. Can you 11 Q. 12 continue your explanation, please? 13 Α. This graph shows in particular the CO/CO2 ratio after the event, and this is adjusted as well for seamgas, so 14 15 it's still using the conservative number for that. We can 16 see a step change around 5 and 6 May where the CO/CO2 ratio does increase. Then we see quite a number of elevated 17 ratios, say, in the 10 days post that, after the explosion, 18 19 and then the CO/CO2 ratio returns down to levels that it was on 5 or 6 May or thereabouts, and it's steady until 20 early June. 21 22 So because we don't have a lot of data for the goaf 23 stream before and after the event, if we were to attempt to 24 25 use this to determine any sort of intensity, we can see that the Graham's ratios in May correlate with around that 26 level of CO/CO2 at that time. 27 28 29 CO/CO2 ratio can - initially at lower temperatures, it will show a larger increase in CO compared to CO2, but as 30 31 the intensity increases, it may be a little bit lower as the level of carbon dioxide production catches up to the CO 32 production. 33 34 But, in general, one of the main takeaways out of this 35 graph is just because the CO/CO2 is at a level, you know, 36 37 at that, the associated Graham's ratio with that shows that there could be an elevated intensity at quite a significant 38 level with those numbers. 39 40 41 Are you talking about at both the point of 5 May, or Q. thereabouts, and then also in early June? 42 43 Yes, that's right. It seems like the - well, from mid Α. and late May the CO/CO2 levels are similar to what they 44 45 were on 5 and 6 May. 46 47 Q. That tells us a bit about the intensity. It doesn't

1 tell us anything about the size of the heat, though, does 2 it? 3 Α. Yes, that's right. The size of the heating, the 4 CO/CO2 or Graham's ratio increasing could still indicate an increase in size, and that would be because the dilution of 5 the seamgasses or the nitrogen will effectively dilute that 6 7 ratio, and as the size of the heating increases, it may overcome that dilution more and give a larger number. 8 In 9 this case, we can see an increase in the beginning of June, 10 which peaks around 7 or 8 June. 11 12 The next slide is an adjusted CO/CO2 ratio, and it has Q. 13 been done using a carbon dioxide to methane ratio of 0.03. Can you explain why you've done that and what this graph 14 then tells us? 15 16 Α. This is tube bundle data that is just confirming the same trend as the GC data on the previous slide, to show 17 two different ways of measuring the gas - different 18 19 instrument, I should say, different technique. 20 So 0.03 - I've used that as a less conservative 21 22 measure, as opposed to 0.02 which I've used for most of the others. The graph shows that those CO/CO2 levels 23 afterwards are similar to those or lower than the ones that 24 25 we saw before. That doesn't mean that it has to be the There may be several reasons why that 26 same intensity. could not be the case, but it does coincide with those 27 And the reason I've done the 0.03 is in this case, 28 levels. 29 when I wanted to compare this and I was looking more closely at it, I wanted to see what a less conservative 30 31 CO/CO2 measurement looked like, but there's still not necessarily the maximum CO/CO2 ratio. It could have been 32 much higher, like 0.04, 0.05, in other sections of the 33 34 mine, so it's still fairly conservative. 35 For present purposes, does the assumption you've made 36 Q. 37 suggest that this trend that I'm showing here with the cursor is not valid? 38 Sorry? 39 Α. 40 41 Is the apparent trend that I'm seeing --Q. Yes, there's an increasing trend. 42 Α. 43 Is that valid? 44 Q. 45 Yes, there's an increasing trend on the tube bundle Α. 46 and as well as the GC - they support each other there. 47

1 Q. In terms of working out the size of the heating, did 2 you look at the CO make figure? CO make is a better indication of the quantity 3 Α. Yes. 4 or the extent or the amount of carbon monoxide being produced as opposed to the intensity. 5 CO make that's high could be a result of a large area of coal at a low 6 7 temperature, or it could be a smaller amount at a higher But either way, the total amount of CO 8 temperature. there's going down the tailgate is being taken into account 9 with the ventilation quantity to give a value there. 10 11 12 So we can see the CO make on this graph has a bit of 13 a step change after the event, similar to that slight increase that there was on the CO/CO2 graphs, and then it 14 sits around the same level from post event until early 15 16 June. 17 So the Graham's ratio at around 1 shows that that's 18 19 a significant heating, and the CO make associated with that shows that that heating is not necessarily increasing in 20 size to any extent, or any significant extent, until early 21 22 June, when it rapidly increases and becomes very obvious, and you can see by the trend there the CO make increases by 23 at least four times in June. 24 25 26 The fact that the CO make is relatively consistent and it's below 40 litres per minute might indicate - and in 27 comparison to that rapid acceleration in early June, it 28 could indicate that if there's a heating present there, 29 that it's not increasing in size or extent of carbon 30 31 monoxide production during that period. 32 33 Does it tell us that there was anything materially Q. 34 different occurring in the goaf at those two separate points in time respectively? We've got the period here 35 from April, where CO make is around 20, or thereabouts, 36 37 just below, and just above 20 litres a minute --Α. Yes. 38 39 40 Q. -- and then it goes to 35 to 40, and so forth? Yes, that's right. That is a step change there. 41 Α. You do need to take into account that quite a few of those 42 43 wells were turned off post event, so those wells may have been removing some CO from the goaf that then ended up in 44 the tailgate, but there is a step change there apparent. 45 46 47 Also, I should have pointed out with the previous

slides as well, with the CO/CO2 ratio, we can see that 1 2 region around - sorry, the one before that - mid-April, where we can see an increase in CO/CO2 ratio around 3 4 mid-April, and we can also see an increase around mid to late March, and those increases in CO/CO2 correlate with 5 6 gas skid data where we see increased CO produced from gas 7 wells close to those locations, or close - they were measuring during those time periods. 8 9 That's the evidence of the witness. 10 MR HUNTER: Thank you. 11 12 13 THE CHAIRPERSON: Yes, thank you. Mr Holt, are you happy to start now? 14 15 16 MR HOLT: I can cover one topic easily before 1, if I may. 17 THE CHAIRPERSON: Yes. 18 19 <EXAMINATION BY MR HOLT: 20 21 MR HOLT: 22 Q. Good afternoon, Mr Muller. My name is 23 Saul Holt. I'm one of the barristers for the Anglo entities who have been given leave to appear. I will try 24 and deal with one topic before lunch - I know you have had 25 a long morning - and then we will come back after lunch. 26 Α. Yes. 27 28 I just want to get clear the way in which the reports 29 Q. that you and Mr Watkinson have completed - the sequence of 30 events in which they worked. 31 I'm right, aren't I, that both you and Mr Watkinson each prepared an initial report? 32 Α. Yes. 33 34 And each of you was - I don't mean this critically at 35 Q. all - the reviewer for each other's report? 36 Yes, but not the only reviewer. 37 Α. 38 I understand that and I'm not being critical. 39 Q. I'm not 40 suggesting that's a problem. It was entirely appropriate and it would be completely normal for someone else at 41 Simtars to review a report created by either you or 42 43 Mr Watkinson? 44 Α. Mmm-hmm. 45 46 So you're obviously familiar with the content of Q. Mr Watkinson's report from your review process? 47

Α. Yes. 1 2 And, indeed, the two of you were doing similar things 3 Q. but from a slightly different data set and with obviously 4 a different focus in terms of expertise? 5 6 Yes. Α. 7 And just to be clear, in terms of Mr Watkinson's 8 Q. report, as he explained to us yesterday, Mr Watkinson's 9 report was focused essentially on data as it was available 10 to the mine, that is, without any reprocessing or the 11 application of adjustments of the kind that you've been 12 13 describing today? 14 Α. Yes, that's right. 15 16 Q. And your report, by contrast, was looking specifically, given your expertise, at the gas 17 chromatographic data? 18 19 Α. Yes. 20 And for the purposes of your first report, some of the 21 Q. 22 reprocessing that you've described was done - yes? Α. Yes. 23 24 25 I'm asking you to say "yes" because of the transcript, Q. 26 so I'm not trying to be rude. 27 Α. Sorry. 28 And, in particular, in addition, you did some of the 29 Q. adjustments, the methane free adjustments and those other 30 31 adjustments, you also did to that data for the purposes of your first report? 32 That's correct. 33 Α. 34 Then, just so we get the sequence right, you and 35 Q. Mr Watkinson do a joint addendum report called "Addendum 36 37 Report 1"? Α. Yes. 38 39 And then you do a second addendum report for these 40 Q. purposes called "Addendum Report 2A"? 41 Yes. Α. 42 43 44 There was a 2, but it was relatively minor issues? Q. That's correct. Just those graphs I pointed out to 45 Α. 46 Jeff already. 47

1 Q. I understand. Thank you. And that 2A report essentially asked you to look at the goaf - what you did in 2 addition to what you'd done in your first report was to 3 look at the drainage holes, analysis that had come from the 4 drainage holes? 5 6 That's correct, and also the size and intensity of Α. 7 potential heating as well. 8 9 Yes, you were asked specifically about that question, Q. and in order to do that, you went back and looked at some 10 of the other data you'd previously looked at? 11 12 Α. Yes. 13 And also some of the data that Mr Watkinson had looked 14 Q. at as well? 15 16 Α. Yes. 17 Now, if we can just get to this 18 Q. All right, thank you. 19 point prior to lunch, if we go to your first report, so at that point you've had chromatographic data reprocessed by 20 analysts or chemists at Simtars - yes? 21 22 Α. On the first report, yes. 23 And you've also done some of the adjustments to some 24 Q. of the data that you've explained to us very helpfully 25 today? 26 Α. Yes. 27 28 If we can have a look, please, at your report 29 Q. MSE.001.001.0005, Mr Operator --30 31 Which one is that, sorry? Α. 32 Your first report. We'll bring it up on the screen, 33 Q. but you're welcome to use your hard copy, if that's easier. 34 Could we go to 0009, please, Mr Operator. This is your 35 executive summary, a page of your executive summary from 36 37 that report? Yes. 38 Α. 39 If we can look down to "Conclusions", please, what 40 Q. you've said there, based on your analysis of that data was: 41 42 43 Despite the lack of obvious signs of accelerating oxidation immediately prior to 44 May 6, the possibility that the ignition 45 46 source for the first event was from spontaneous combustion should not be 47

1 dismissed ... 2 3 And then you give a range of reasons - yes? 4 Α. Yes. 5 6 So may we take it, then - it just flows as a matter of Q. logic - that as at the time of your first report there was 7 a lack of obvious signs of accelerating oxidation prior to 8 6 May, on the basis of the data that you'd seen? 9 Well, yes, I still - you know "obvious" - the stuff 10 Α. that we'd gone through beforehand, even in the second one, 11 there's nothing that's really obvious that I --12 13 14 I was going to come to that, but I want to take it Q. stepwise, though, if we may. On the basis of that set of 15 16 data that you had looked at, which was the data from the mine, re-looked at by your chemists and with the benefit of 17 the various adjustments that you had made, that was still 18 19 the conclusion that you came to? After looking at more of the skids a bit 20 Α. Yes. closely, there was a few things that I noticed in there. 21 22 I understand. For the second report? 23 Q. Α. Yes. 24 25 26 Q. I understand. We'll come back to the second report, I promise. And you're aware also, I imagine, having 27 reviewed Mr Watkinson's report, of his conclusions about 28 the datasets that he had looked at about the first 29 400 metres of retreat of longwall 104? 30 31 Α. Mmm-hmm. 32 Do you take any issues with those, did you disagree 33 Q. 34 with any of his conclusions? I'm not familiar with that report. Which report was 35 Α. that, sorry? 36 37 Q. His first report. 38 Is that the one on - is that a methane exceedances one 39 Α. 40 or the spontaneous combustion? 41 Q. 42 No, spontaneous combustion. 43 Α. Yes. 44 45 I have a couple of minutes. I might try to use the Q. 46 time. In terms, then, of the work that you did with the data that had come from the mine, the reprocessing involved 47

actual chemists from Simtars, trained chemists, looking at 1 the gas chromatographic data - yes? 2 Yes. 3 Α. 4 And looking at it closely, zooming in on places of 5 Q. 6 interest, that sort of thing? Yes, that's right. In particular, like, the ethylene. 7 Α. 8 9 In particular at the ethylene? Q. Well, yes, yes, checking those sorts of things, yes. 10 Α. 11 12 We'll come back to the ethylene after lunch. The Q. 13 other thing you did was you applied methane free calculations to a number of the ratios in particular, the 14 15 results of the ratios? 16 Α. Methane - I applied methane free to some of the gas 17 skid data. 18 19 In order to effectively take a different approach or Q. which led us to the different sets of results that we've 20 seen because you applied that technique of methane free? 21 22 Α. Yes, that's right. 23 And, in addition, specifically in relation to Graham's 24 Q. 25 ratio, you applied a long form of Graham's ratio rather than a short form of Graham's ratio - yes? 26 Α. Yes. 27 28 29 Can we deal with the short form versus long form of Q. Graham's ratio now, because I think I can do that in the 30 31 minute or two I have before lunch. The system that operates at the mine uses the short form of Graham's ratio; 32 is that right? 33 Well, it depends on what system you're talking about. 34 Α. The software that the data can be input to that goes with 35 the gas chromatograph, that would usually give the option 36 37 of using a Graham's ratio relevant for a tube bundle or for a GC, which would be the short form, or one of the shorter 38 forms that isn't the long form. I'm not sure exactly where 39 those values would come from when they're interpreted by 40 the mine. They could also have a spreadsheet that would 41 calculate that for them. 42 43 44 Those software packages you're talking about are Q. Simtars software packages are they not? 45 46 Α. Yes. 47

1 Q. And, in fact, you personally do the training of people on the various mine sites in those packages? 2 Yes. 3 Α. 4 As you've noted, they use the short form of Graham's 5 Q. 6 ratio, and you train people to use that? Or you train people to use the software which has that setting in it? 7 Yes, yes, but Graham's ratio could be calculated in 8 Α. many different ways at different mine sites. 9 The software. as far as I know - the software that collects that data 10 might not always be the way that the mine wants to collect 11 that data, if that makes sense. 12 13 14 Sure, but the way that the software is set up by Q. 15 Simtars at Grosvenor and trained by you uses the short 16 form, does it not? Well, yes, the short form is the - you know, you get 17 Α. the tube bundle or the GC form as an option in the 18 19 software. 20 MR HOLT: Is that an appropriate time, Mr Martin? 21 22 THE CHAIRPERSON: It is. We will have to adjourn until 23 2.30 today, if you don't mind. We will be back then. 24 25 Thank you. 26 LUNCHEON ADJOURNMENT 27 28 Mr Muller, just before the break, we had 29 MR HOLT: Q. begun talking about the steps that you took with the data 30 31 that had come out of the mine systems to make the adjustments, and so on, that you made to try to understand 32 the data better - yes? 33 Yes. 34 Α. 35 In terms of Graham's ratio, as we discussed before 36 Q. 37 lunch, you went to a long form of Graham's ratio? Yes, that's right. 38 Α. 39 40 Q. In terms of that, we were talking about the way in which the Simtars systems on site, the software on site, 41 deals with Graham's ratio, and I just want to be completely 42 43 clear. It's right, isn't it, that the Simtars systems on site only have the capacity to do short form Graham's 44 ratio, and if a mine wants to do long form Graham's ratio, 45 46 they will need to get someone like you to come along and do it afterwards? 47

Not necessarily. The GC as it is, it doesn't do any 1 Α. 2 Graham's ratio. It just prints out raw data. Then there's software called Segas, and there's a software - there's 3 a dump from the GC of that data into Segas, and using 4 Segas, the default equations that you can get from that 5 6 would involve the theoretical air, oxygen, nitrogen ratios. 7 There is an option to put in a custom ratio. 8 9 In the case of the GC data, that might be a bit of a manual process to have to update frequently. 10 11 12 Simtars comes on site and sets the software up and Q. does the training, and so on, doesn't it? 13 We do GC training, yes, and we would do other 14 Α. 15 training, for example, spontaneous combustion training, but 16 that would be in a separate training session. It's not the same - GC training wouldn't involve training on all these 17 different ratios, and as the control room operators or 18 19 whoever is using the GC, that might not be as appropriate, and we would go through all of that in a more advanced 20 spontaneous combustion training session. 21 22 23 Then, in addition, you made some changes to make some Q. of the analysis that you did methane free, as we discussed 24 25 just before lunch as well? Yes. 26 Α. 27 28 Q. What are the downsides of doing that? What are the risks in terms of doing a methane free analysis compared to 29 a raw data analysis? 30 31 If you had a location that was monitoring very high Α. methane - I'm just arbitrarily picking numbers here, but 32 let's say 90 per cent or more - and then you had a low CO, 33 34 arbitrarily maybe 1 or 2 or 3, the difference between those sensors, and as you've seen with the analysis that I've 35 done for number 8, where I had to correct it to make it 36 37 lower than it was, you know, that's a 50 per cent difference at, like, 100 ppm, so if you take into account 38 some of the discrepancy that could be on the sensors, if 39 you have a reading very low, like 2 or 3 or 4 or 5, the 40 difference in response for the sensor at those levels is -41 you could easily magnify that number beyond what would make 42 43 sense at a high methane concentration. 44 Then again, too, if that methane sensor was reading 45 46 incorrectly and particularly if it was reading incorrectly high, it could magnify that back and give a false alarm. 47

So for that sort of set-up to be practical, I think there 1 would have to be some work done to try and determine some 2 sort of limits as to what ranges that is appropriate and 3 what ranges it's not. I mean, with all ratios, they have 4 their limitations, which is why it's difficult - say for 5 the adjusted CO/CO2, there's different CO2 concentration on 6 different sections, or it might change as time changes or 7 it might be hard to distinguish what's from the seamgas and 8 what's not. 9 So --10 That's exactly one of the issues I think that you 11 Q. identified in your report around the adjustment that you 12 13 made to the CO/CO2 ratio to account for seamgas? So that's another thing that could be difficult 14 Α. Yes. to have an updated, what the best number is for that. 15 16 Maybe a conservative number would be possible. If vou could say what's the - like, when I looked at the data. 17 0.02 was about the lowest that I could find, so that's what 18 19 I used. If you were using numbers that were much higher than that, then you could distort the ratio if they were 20 too high by mistake, and then you could get false alarms in 21 22 that sense. 23 In terms, then, if we can come out of 24 Q. I understand. that detail for a moment and just talk about the markers or 25 the tools that are used by site and the tools that have 26 been used by you and Mr Watkinson in your report to look 27 for signs of oxidation, if we work through them as a list, 28 we have Graham's ratio, as we've been discussing? 29 Yes. 30 Α. 31 CO/CO2 ratio? 32 Q. Yes. 33 Α. 34 Q. CO make? 35 Α. Yes. 36 37 Q. CO concentration? 38 Α. Yes. 39 40 And we've been discussing, or you've been discussing 41 Q. this morning, also the presence of ethylene? 42 43 Α. Yes. 44 45 Any others of significance - I think I've covered them Q. 46 all? 47 Α. Hydrogen is often relevant.

1 2 One of the reasons, though, why hydrogen has become Q. less relevant over time is because guite a while ago, 10, 3 4 20 years ago, it was thought genuinely that the presence of any hydrogen indicated a very high temperature of coal, 5 6 didn't it? Mmm. 7 Α. 8 9 One of the things that's happened over time as gas Q. evolution testing has got more sophisticated and been able 10 to test for lower and lower levels of hydrogen is that it's 11 12 become clear that hydrogen is present at much lower 13 temperatures of coal than was originally thought? Yes, that certainly hasn't - I haven't been in the 14 Α. industry long enough to have been around at that time, but 15 16 from what I understand, say if the lower limit of detection for hydrogen used to be 50 ppm, if we look at this data 17 now, by the time there's 50 ppm, that's big trouble. 18 19 20 Q. Exactly. So that doesn't mean that it's not useful. 21 Α. It just 22 means that we are looking at different numbers and we're 23 looking at trends. So there might be a base level of hydrogen in goaf or in air, or whatever, that could be 24 between 1 and 10, depending on the mine and depending on 25 the gas and that sort of thing, so increases beyond 26 whatever would be normal there are still appropriate. 27 And 28 in terms of when an oxidation increases to possibly a fire or something very, very hot, then you'd expect to see that 29 hydrogen ratio shoot right off, and then it's very obvious 30 31 and it's almost - when it equals the level of CO, that's often a sign that something's --32 33 34 Q. Yes, and what this shows is the sensibleness, if that's even a word, of using these multiple tools to look 35 at the same environment in lots of different ways through 36 37 lots of different lenses? Yes, that's right. 38 Α. 39 40 Q. What it allows you to do is to look at combinations of locations and combinations of results of those tools: 41 right? 42 Combinations of locations? 43 Α. 44 45 Locations of, for example, where gas is taken from, so Q. 46 you can see relationships physically between different results from different places in a longwall? 47

1 Α. Yes, yes. There's different locations. There's also the same - you could use different techniques to measure 2 the same location - for example, the real-time versus the 3 4 gas chromatograph is a different technique --5 6 I talked with Mr Watkinson yesterday about TARPs and Q. 7 the development of TARPs and how those levels are developed in the kind of structure that's presently used in 8 9 Queensland. Have you had any involvement yourself in your career with the development of TARP levels and the design 10 of TARPs in longwall mines? 11 12 Not in longwall mines. I've done some simple TARPs, Α. say, for open-cut or more hygiene related things, which 13 general body contaminants --14 15 16 Q. You understand I'm sure the basic proposition, which is you have TARP levels, and each level has within it 17 certain triggers, basically, that tell you whether you're 18 in normal or TARP 1, TARP 2 or TARP 3? 19 Yes, I'm familiar with looking at TARPs. 20 Α. 21 22 Q. Part of the process of developing TARPs is to make 23 sure that you have measures or triggers which are robust enough to identify the abnormal, but at the same time you 24 don't want to have TARP levels that are just going to be 25 26 triggering off all the time because people get sensitised to them? 27 28 Α. Yes, that's right. I think there's a balance with 29 that. 30 31 In terms of spontaneous combustion TARPs, one of the Q. techniques in the sophisticated development of TARPs is to 32 say, "Well, at each TARP level, what do we want these 33 different measures to be telling us about the temperature 34 of the coal" - yes? 35 Yes, I suppose, yes. 36 Α. 37 That's where gas evolution testing comes in, right? 38 Q. Because gas evolution testing is aimed to tell us 39 40 particularly at a site-specific level, what the CO/CO2 ratio might be when the coal is at 70 degrees or 80 degrees 41 or 100 degrees? 42 43 The gas evolution could be used as a guide - for Α. 44 example, I pointed out before that the ethylene might appear on the gas evolution at 100 degrees or 80 or 120, 45 46 depending on the gas. I think the limitation with the gas evolution is that it's an artificial test in terms of it's 47

a very small amount of coal that's put in a little kind of 1 oven that's used to heat it all uniformly, with a set 2 airflow, and the numbers that you get out of that might not 3 always correlate to the numbers that you would see in the 4 coal mine. 5 6 7 Q. And that's exactly why you would also use other datasets like, for example, textbook values to compare 8 against what you're getting from your gas evolution testing 9 10 locally? Yes, but also real data. In my experience, I've seen 11 Α. 12 a lot of spontaneous combustions where I look at the gas 13 ratios and then I look at the textbook and then I look at 14 the gas evolution, and none of it adds up, so --15 16 Q. If you just give me a chance. And you'd also look at the mine specific data, for example, where you've had 17 previous longwall panels - you'd get data from as many of 18 19 those different sources as possible to identify what your various TARP trigger levels would be? It's a pretty basic 20 proposition, isn't it? 21 22 Α. Yes. 23 Sensibly, you'd also get expert assistance in, as well 24 Q. as using your own internal expertise, as a mine? 25 26 Α. Sorry, say again? 27 28 Q. Sensibly, you'd also get external expertise in, as well as using your own internal expertise, as a mine 29 operator --30 31 If you're the mine, you would get --Α. 32 -- to develop your spontaneous combustion TARP. You 33 Q. would get external expertise, as well as using your 34 internal expertise, to help you develop, using all of those 35 various data sources, a TARP specific to your local 36 37 environment? Well, yes, if you're the mine I suppose you'd get any 38 Α. expertise you can to help you with that sort of thing. 39 40 Let's just talk for a moment, please, about ethylene. 41 Q. Can we test this proposition: similar to hydrogen, it was 42 43 once widely thought, wasn't it, that ethylene only appears at all when coal is at about 100 degrees? 44 I'm not sure what you mean by "once". 45 Α. 46 47 Q. Once thought, as in the knowledge in that area has

developed since people held that view, and it's becoming 1 2 clear, in fact, that ethylene is produced potentially at lower temperatures than that? 3 I wouldn't necessarily agree with that. 4 Α. 5 I don't know what that means. What do you mean 6 Q. "I wouldn't necessarily agree"? 7 Well, I haven't been shown any data that says that 8 Α. ethylene is produced at a lower temperature and "here it 9 is". Like I was talking about, before, there could be 10 different GCs that are set up differently and could detect 11 it at much lower levels, but with the particular GCs that 12 13 we use, which would be similar to the ones that the gas evolution would be done on, it seems to appear around that 14 And if we are comparing what tool is used in 15 temperature. 16 the mine site compared to what tests are done. I think that's a relevant thing there. 17 18 19 So I haven't seen any references where that particular 20 GC is identifying ethylene at a lower temperature than that. 21 22 23 Q. Mr Hunter was referring you to timber, green timber, in particular, I think he referred to green timber 24 underground. Are you aware of that work that's being done 25 by Simtars at the moment in the development of what's 26 27 ultimately to be an ACARP report? 28 Α. Yes. 29 Are you aware that one of the reasons for doing that 30 Q. 31 wasn't just related to the presence of green timber but was part of an exploration of the fact that ethylene is being 32 found regularly at very low levels in coal mines in 33 34 circumstances where there are no other indicators of 100 degree temperatures, for example? 35 Α. I think that ethylene has - from what I've seen, there 36 37 might be something to show that ethylene can come off from I'm slightly concerned that it could become an 38 wood. excuse, as to, you know, an explanation, "Why are we seeing 39 40 ethylene?" "Oh, it's from the wood." 41 The circumstances where I've seen it have been in 42 43 a goaf that's been sealed and there has been no other 44 carbon monoxide associated with that ethylene, so it was fairly clear that there was ethylene there, but there was 45 46 no indication of other oxidation activity and there hadn't been any for some time, so that's a bit of a different 47

1 circumstance to when you could be getting a sample that has 100 ppm of ethylene and then - sorry, 100 ppm of carbon 2 monoxide and then it has ethylene associated with it. 3 4 Just dealing, then, with ethylene 5 Q. I see. Thank you. 6 itself and the way in which you detect ethylene on the gas chromatograph, you spoke with Mr Hunter about a concept 7 called - I think he raised it with you - the limit of 8 detection? 9 Α. Yes. 10 11 12 And the limit of detection for ethylene for Simtars, a Q. 13 NATA accredited laboratory, is 1 part per million - that's what you said this morning? 14 The limit of detection is - yes, that's what we would 15 Α. 16 use if that's what the instrument is validated at, which is what we would normally validate the instruments at. 17 18 So the answer to my question, is the limit of 19 Q. detection at Simtars for ethylene 1 part per million - is 20 the answer to that question "yes"? 21 22 Α. If I were able to mix half a ppm or lower, I might be able to get a limit of detection out of that. But with the 23 mixing equipment available, we're mixing 1 ppm, so it's not 24 necessarily based on the instrument itself, either. It's 25 the limits of our mixing, because to get that reference 26 point, we have to have a proper reference gas to be able to 27 28 test that against. 29 Let's try another concept and see if we can make it 30 Q. 31 a bit easier. As well as limit of detection, there's a concept called limit of reporting? 32 Α. Yes. 33 34 And limit of reporting is what a NATA accredited 35 Q. laboratory like Simtars identifies as the level at which it 36 will report, by its own chemists, people like you and your 37 team, no doubt, to clients when they get it to do a report 38 on a gas sample; right? 39 Yes, but generally the NATA accreditation and the work 40 Α. we would do under our NATA accreditation is not for coal 41 mines, because the coal mine GC is set up on the coal mine 42 43 site. They don't send us samples, so --44 45 I'm not asking that question. For NATA accreditation Q. 46 you identify, don't you, when you're providing results, a limit of reporting and a limit of detection, and they are 47

1 two different things - yes? 2 We specify limit of reporting. Α. 3 And what is Simtars' limit of reporting for ethylene 4 Q. 5 from a GC? 6 Well, on our current reports, it's 20 ppm, which is Α. far in excess of what the capability is of the instrument 7 and what we would provide to the mine site. 8 9 10 Q. I understand that, but part of the process of NATA accreditation and ensuring that there is a level of 11 12 confidence in results is that the limit of reporting is 13 intended, isn't it, to identify effectively the practical limit of quantification of a particular --14 Yes, for the quantification, and, like I said before, 15 Α. 16 when you've got lower levels of ethylene, like 0.2 or 0.3, it might not really be that number. So at 20 ppm, it's 17 a lot easier to say under those NATA accredited procedures 18 19 that that level has a certain uncertainty associated with being able to guarantee that to --20 21 22 And that uncertainty, what's called the measurement Q. uncertainty, that must be reported in relation to that, for 23 Simtars, even at that 20 ppm, is 15 per cent, isn't it? 24 25 I can't remember off the top of my head, but it's not Α. really relevant to - it's very different work from what 26 happens in the laboratory under the NATA accredited - not 27 very different, but that's like a kind of part of the 28 paperwork for the NATA process. It's not really relevant 29 to what we do on the mine site. 30 31 32 Q. You use the same GCs for the purposes of doing your Simtars reports which have the 20 ppm limit of reporting as 33 34 are on the mine sites, don't you? Well, we have different GCs in the Simtars lab. 35 Α. They're not all the same, so that's part of the reason. 36 We 37 could be using a different GC that's not capable of doing We could have different GCs that are optimised for 38 that. different purposes that might be more appropriate for 39 40 a particular job that's done in the laboratory. 41 In any event, sitting below the limit of reporting is 42 Q. 43 the limit of detection, which is 1 part per million? 44 Α. Yes. 45 46 Q. Can you tell me, please, because there are two ways, aren't there, in which a limit of detection is determined 47

through the NATA process - one is a method detection limit 1 2 and the other one is an instrumental detection limit - do you know which the 1 ppm stems from? 3 I'm not sure that I understand what you're asking. 4 Α. We would test each instrument individually for a 1 ppm limit 5 6 of detection. 7 We'll move on and try to practicalise that. 8 Q. Can we have up Mr Hunter's PowerPoint, please, and could we have 9 a look - we'll just go through a few of these slides. 10 I'11 identify some issues related to things I've already talked 11 to you about. Could we go first to slide 4. 12 13 14 You were taken through a series of slides - and I'll go through them briefly as well - by Mr Hunter of this 15 16 table, which sets out what were put to you as effectively significant combinations of results of those various tools 17 that have been used over the period relevant to this 18 19 Inquiry? Α. Yes. 20 21 22 Q. And you very helpfully identified that some of these measures in fact have since changed - some of these results 23 have since changed by virtue of the later work that you did 24 particularly around the Graham's ratio? 25 You mean I've reprocessed to get a different value for 26 Α. the Graham's ratio, for example? 27 28 Yes. 29 Q. Α. Yes. 30 31 Let's have a look at that. We can see if we look at 32 Q. the table we have obviously got date and time - that's easy 33 34 enough - and then we have the Graham's ratio, 0.2 and so on Let's just take the top line, CO parts 35 and so forth. per million at 42, and then where there's an ethylene 36 detection, you've noted that as well, and then notes for 37 other reasons; right? 38 Α. Yes. 39 40 A Graham's ratio at - you've used as the significant 41 Q. cut-off for normal for your analysis Graham's ratio 0.3? 42 43 Yes, but I've still mentioned it there if there's Α. something else that's been - like, for example, if there's 44 something that's high in CO or I've detected ethylene, I've 45 46 still put the Graham's ratio there as well for reference. 47

1 Q. I can see that. I'm just asking the question, the threshold that you've used for normal for the purposes of 2 your analysis for Graham's ratio is 0.3? 3 4 Α. Yes. 5 6 You've done that because that's the level that the Q. mine has chosen for its TARP? 7 Α. Yes. 8 9 10 Q. Though you note that the textbook value for that is in fact higher, at 0.4, than the mine site has chosen to use, 11 12 at 0.3? 13 Α. Yes, that's correct. 14 15 So in that context you've chosen to go with the mine's Q. 16 number rather than the textbook value? Yes. Α. 17 18 19 We'll just work down. If we look, then, at Graham's Q. ratio at 0.2 for 17 March, on either measure - that is, 0.3 20 or 0.2 - that is sitting - well, if it's, sorry, 0.3 or 21 0.4, it's sitting in the normal range? 22 Sorry? Oh, is the 0.2 in the normal range? 23 Α. 24 Q. Yes. 25 26 Α. Yes, according to the TARPs. 27 28 Q. And CO parts per million, the normal range in the TARPs is 100 parts per million? 29 For what parameter? 30 Α. 31 I think for all. I can't see anything lower than 32 Q. that. 33 34 Α. Is this the goaf stream? Because I don't see a specific goaf stream on the TARP. 35 36 37 So what's the point that's trying to be made by having Q. the 42 - what's the significance of 42 in CO parts per 38 million in this table in relation to the goaf stream? 39 That could be - on 17 March? 40 Α. 41 Q. Yes. 42 43 So that could have been because when I've reprocessed Α. 44 it, maybe the Graham's ratio is higher, because when I originally did this table, I kept everything together, 45 46 but then we decided that maybe it was better to separate out what I had done and what the mine had done. 47 So it

could be either that or, otherwise, if that's not down in 1 the other table down the bottom, then I'm not sure. 2 3 4 The Graham's ratio as you've reprocessed it using your Q. table 5.5 for that measure is 0.23, so it's barely 5 6 different? Yes, that's right, I'm not sure why that's there, 7 Α. then. 8 9 10 Q. Thank you. Could we then go to 19 March, where there's a note about diesel operating. Do you see that? 11 12 Α. Mmm-hmm. 13 I may have misheard you: was it actually your 14 Q. evidence that diesel engines don't produce ethylene or that 15 16 you wouldn't expect to see the consequence of the ethylene produced by a diesel engine, or don't you know? 17 Yes, by the time dilution occurred, I wouldn't expect 18 Α. to detect it unless there was something majorly wrong with 19 the engine or something. 20 21 22 Q. Because diesel engines do produce ethylene, don't 23 thev? I haven't seen a lot of - well, I haven't analysed 24 Α. a lot of gases from a diesel engine. 25 26 27 So how would you then possibly be in a position to Q. proffer an opinion about whether the ethylene that came 28 from a diesel engine might be diluted such that you 29 wouldn't see ethylene in that parts per million in this 30 31 result if you don't know what that concentration would look 32 like? Well, I have analysed gases from some engines on cars, 33 Α. 34 and the amount of ethylene that comes out, if you see any, and I've rarely seen it, but it might be not very high, so 35 considering the - maybe it's not my expertise being 36 37 a ventilation person, but the amount of exhaust coming out compared to the ventilation quantities --38 39 40 Q. If we go to 20 March - we're not doing all of them, I'm just going to pick some examples - you can see 0.95 is 41 the Graham's ratio? 42 43 Α. 20 March? 44 45 Q. Yes, at 14:15 hours. Can you see that? 46 Α. Yes. 47

.18/03/2021 (19) Transcript produced by Epiq © Copyright State of Queensland (Queensland Coal Mining Board of Inquiry) 2020

1 Q. That was one that you pointed out to Mr Hunter had in fact been reprocessed to what you considered to be a more 2 accurate result, which by reference to your table 5.5 is in 3 4 fact 0.31? Yes, that's correct. 5 Α. 6 And indeed we'll do this a little more on the next 7 Q. page, but if we keep going down the ethylene column, we can 8 see there 0.14 ethylene, 0.19, 0.25, 0.18, 0.09 - do you 9 10 see those? Sorry, say again? 11 Α. 12 13 Down the ethylene column, I'm reading out the Q. numbers - 0.14, 0.19, 0.25, 0.18, 0.09? 14 Yes. 15 Α. 16 They are all below 1 part per million, that is, the 17 Q. limit of detection? 18 19 Α. Yes. 20 And they're obviously enough something in the order of 21 Q. 22 two orders of magnitude lower than Simtars' own limit of 23 reporting? Well, that's not really relevant to this. 24 Α. 25 26 Q. Are they or not? 27 28 MR HUNTER: With respect, the witness gave an answer before about this and he explained that the limit of 29 reporting related to reporting made by Simtars using its 30 equipment. He's talking about, that is, the witness, is 31 talking about reporting based upon data taken from the mine 32 itself. 33 34 MR HOLT: I'm happy to leave it, Mr Martin. 35 36 37 THE CHAIRPERSON: Yes, thank you. 38 39 MR HOLT: Q. In terms of the capacity to pick up ethylene at those kinds of levels, the people in the 40 control room are the people who are trained by Simtars and 41 often by you? 42 43 Yes, there's other people. It's not only control room Α. 44 operators. 45 46 Q. Sure, but they're trained by Simtars and often by you? 47 Α. Yes.

1 2 Q. If we then go down, please, to the next page, Mr Operator, we're now at tailgate 104, C heading, 3 40-41 cut-through. Can you see that? 4 Α. Yes. 5 6 7 Q. We can see here again a series of Graham's ratios, the 0.38 is above normal, so it will be in TARP level 1 for the 8 9 mine - yes? If the - what - oh, this is the - yes, this is the 10 Α. seal, so yes. 11 12 13 Q. We can see there CO parts per million, 139 parts per 14 million? Yes. 15 Α. 16 And again that would take us up, wouldn't it, into 17 Q. TARP level 1? 18 19 Α. I believe so. It's 130, is it, for level 1? 20 Yes, so 9 over that. And then the ethylene again we 21 Q. 22 can see, less than 1 part per million? Yes. 23 Α. 24 25 Almost an order of magnitude less than 1 part Q. per million? 26 Α. Yes. 27 28 A CO/CO2 ratio of 0.02; we see that, don't we? 29 Q. Α. Yes. 30 31 32 Q. You've taken that, as you've noted in your report, purely from a textbook value of 0.02? 33 34 Α. Yes. 35 Now, you would expect, wouldn't you, that a CO/CO2 36 Q. 37 ratio for the mine would be derived, unquestionably, with reference to textbook values but also paying significant 38 regard to the testing of the actual coal on the site? 39 40 Α. Yes, but also the seamgas effect as well. 41 If it turns out that 0.02, as a CO/CO2 ratio, would in 42 Q. 43 fact, on the analysis done, end up something in the order of 50 degrees for coal, would that change your view as to 44 the appropriateness of simply grabbing the textbook value 45 46 of 0.02? 47 Well, not really, because there's so much dilution Α.

involved in any of the samples, potentially, it's hard to 1 I mean, this sample is being taken from a point 2 tell. underground that could be any distance away from where this 3 is being generated, and there's a lot of other gas that it 4 would mix in with. So just to go, "Oh, that's the number 5 that adds up with the table", I think that would - you 6 know, I'd see that as an "at least" number, not an 7 indicator of what temperature it actually is. 8 9 But again, one of the last things that you want to do 10 Q. with a TARP is to be in TARP all the time, because that 11 12 means that people get normalised to it? 13 Α. Well, that's true too, but like I said before, there's a balance, too. So you also need to be able to recognise 14 data that is important. 15 16 Unquestionably. Can we have a look, please, at 17 Q. No, I'm sorry, could we go down to slide 13, slide 12. 18 please. This is showing long form Graham's ratio, so this 19 is the work that was done by you with the data that had 20 come from the systems on the mine, but afterwards, right? 21 22 Α. Yes, that's correct. 23 With the complexities associated with that that we've 24 Q. already discussed? 25 Yes. 26 Α. 27 28 Q. Could you tell me this, please: with the short form ratio - that is, with the data as it came out from the 29 mine, which Mr Watkinson talked to us about yesterday - we 30 31 don't see, do we, the big step-up, or the step-up that occurs either side of that big point? 32 I don't believe so. 33 Α. 34 Can you explain why that might be so in terms of the 35 Q. way in which the long form Graham's ratio might have 36 37 affected those outputs? 38 MR HUNTER: With respect, Mr Watkinson's evidence did not 39 relate to the gas chromatogram data from the goaf stream. 40 If my friend is going to make assertions like this to the 41 witness, he should take him to the output or the data that 42 43 was referred to by Mr Watkinson yesterday. 44 45 There was a distinct divergence between the two of 46 One looked at the real-time and tube bundle data and them. one of them looked at the gas chromatograph data. This is 47

1 gas chromatograph data. 2 3 MR HOLT: I'm happy to approach it in a different way. 4 Mr Muller, I think you said - whether it was 5 Q. 6 Mr Watkinson or whether it was you - do you agree with me, and if you don't, it's fine, that before you did the 7 change, that is, before you turned this into a long form 8 Graham's ratio, when you used the short form Graham's 9 ratio, we didn't see that step-up change? 10 I think there was a step-up change, but not as 11 Α. 12 significant. 13 14 Now, can I then move forward, please, to page 16. Q. I just want to be clear about this. Mr Hunter pointed out 15 16 to you, and you agreed, that there is a difficulty with the vertical axis here where numbers appear to be repeated? 17 Yes. Α. 18 19 20 You had indicated that that was a consequence of the Q. number of decimal places which were shown effectively in 21 22 the way in which this graph is presented? That's correct. 23 Α. 24 25 Then Mr Hunter took you to, or I think summarised, the Q. way in which in fact the step-ups should happen, and you 26 agreed with that summary, but it all happened quite 27 28 quickly, so I want to make sure we have it right. The increments ought be, am I right, in increments of 0.005? 29 Yes. 30 Α. 31 So from zero, what says 0.01 should be 0.005 - yes? 32 Q. I believe so, yes. 33 Α. 34 Then the next one up, which currently says 0.01, is 35 Q. correct? 36 37 Α. Yes. 38 Q. Then the next one up should be 0.015? 39 40 Α. Yes. 41 Then the next one up is correct at 0.02? Q. 42 43 Α. Yes. 44 Then again the next one up should be 0.025 - yes? 45 Q. 46 Α. Yes. 47
Q. And then the final one should be 0.03? 1 2 Α. Yes. 3 So for present purposes, and recognising that you've 4 Q. taken 0.02, the textbook value for CO/CO2 ratio, it's 5 6 actually the second one of those lines, isn't it? Yes, that's right. 7 Α. 8 9 Q. That represents the 0.02 normal --That would be 0.015, that line above most of the graph 10 Α. there. 11 12 13 Q. And so obviously enough, if it's the second 0.02, then 14 the values that we can see below the line are further down than they might otherwise initially have appeared - further 15 16 below the line? Yes, yes. 17 Α. 18 19 Again, we see the same issue, don't we, in the next Q. graph, on page 17, which is effectively the same output; 20 it's measuring CO/CO2 ratio at tailgate 104, 21 22 3-4 cut-through, but this is adjusted for seamgas in the way that we discussed before? 23 Yes, that's correct, and that's got the same issue 24 Α. 25 there with the axis that you pointed out there. So it looks like that that should be 0.025 that most of that data 26 is underneath, until it gets to the June data. 27 28 So essentially, if I can short-form this rather than 29 Q. going through the process of correcting each one, it's the 30 31 highest, that is furthest up the page, 0.02, the second entry of that, which actually represents 0.02 in the 32 context of that diagram? 33 34 Α. Yes. 35 Just finally, please, could we go to page 73 of the 36 Q. 37 PowerPoint presentation, which is the very last page. Again, this is CO make, tailgate 104, 3-4 cut-through, 38 March to June. You can see that? 39 Yes. 40 Α. 41 I just want to focus on the period of time to the left 42 Q. 43 of the ellipse that you've drawn on the right-hand side, so essentially that earlier part of the longwall progression. 44 45 Do you see that? 46 Α. Yes. 47

You've identified a line there, 30 to 35 litres per 1 Q. minute? 2 Yes. 3 Α. 4 I haven't heard or seen you say anywhere how that 5 Q. compares to, for example, TARP levels of normal or textbook 6 values of normal? 7 I wasn't comparing that to anything from the textbook 8 Α. or the TARP. I was comparing it to the rest of the data 9 there for a relative indication. 10 11 12 But in fact it assists us, doesn't it, if we look at Q. 13 that 30 to 35 litres per minute line, to understand that it's less than the 42 litres per minute identified in the 14 TARP? 15 Yes, that line is just to give everyone an idea, if 16 Α. the scale is too hard to read, where - not that the small 17 text is any easier to read. 18 19 20 Q. I understand, but in terms of CO make and understanding what that data might mean in terms of the 21 22 actual numbers, it's, obviously enough, less than 42 litres per minute? 23 Yes, I'm taking the 42 - you're talking about the TARP 24 Α. level? 25 26 Q. Yes. 27 28 29 MR HOLT: Thank you, Mr Martin. 30 31 THE CHAIRPERSON: Mr Crawshaw? 32 I don't have any questions, thank you. 33 MR CRAWSHAW: 34 THE CHAIRPERSON: Ms Grant? 35 36 37 MS GRANT: No questions, Mr Martin. 38 THE CHAIRPERSON: Mr O'Brien? 39 40 41 MR O'BRIEN: No, thank you. 42 43 THE CHAIRPERSON: Ms Holliday? 44 <EXAMINATION BY MS HOLLIDAY: 45 46 47 MS HOLLIDAY: Q. Mr Holt asked you in relation to the

Transcript produced by Epiq

1 training that the operators receive in relation to the GC 2 operation. Yes. 3 Α. 4 And he made the point that the operators were trained 5 Q. 6 by Simtars and made the further point that the operators 7 were trained by you. Mmm-hmm. 8 Α. 9 10 Q. When you train the operators, you expect them to zoom in on the relevant graphs? 11 Yes, that's a major focus of the training. 12 Α. 13 14 Mr Operator, if we can go to MSE.001.001.0024. Q. Could we zoom in on figure 14, please, and zoom in on the peak of 15 16 the ethylene underneath the red bar. You train the operators to zoom in on the line, so to speak? 17 That zoom - I'd probably say that's maybe one 18 Α. Yes. too far, what's on the screen there, but if you can see 19 that noise to the left there and then maybe the same 20 distance to the right, then that would give a good 21 22 perspective. 23 We might go back out slightly, Mr Operator, and we'll 24 Q. 25 leave it at that for the time being. So you train the operators to look at the peaks; that's correct? 26 Yes. 27 Α. 28 29 Q. You also train them to cut out the noise, as you call it? 30 31 I train them to try to differentiate between the noise Α. and a peak, which can be difficult, the lower the - you 32 know, the less that peak sticks out of the baseline, it can 33 34 be difficult, until there's a point where you can't see it But, yes, we spend a lot of time repeating that 35 any more. process. 36 37 If an operator had a standard of competence retained 38 Q. from their training, should they have picked up more 39 readings of ethylene than have been detected here in your 40 analvsis? 41 Yes, I'd hope so. I wouldn't expect all of them to be 42 Α. 43 picked up, and maybe some of the smaller ones not, but 44 certainly more of them. 45 46 Q. To be clear, going back to the PowerPoint - we don't 47 need to bring it up at the moment, but you made the point

with Mr Hunter that the asterisks in those first tables 1 2 were the readings of ethylene that were not picked up by the operators; that's what the asterisks represented? 3 4 Α. Yes, yes. 5 The effect of your evidence now is that if the 6 Q. operator had retained from their training the level of 7 competence, you would have expected more of those asterisks 8 to not appear as asterisks? 9 10 Α. Yes. 11 12 MS HOLLIDAY: I have no other questions, thank you, 13 Mr Martin. 14 Yes. Mr Hunter? 15 THE CHAIRPERSON: 16 I have no further questions, thank you. MR HUNTER: 17 18 19 THE CHAIRPERSON: Mr Clough? 20 Mr Muller, I only have one question, and 21 MR CLOUGH: Q. it's a bit outside what we've discussed, but it's something 22 I've come across in reading papers, and it's the notion of 23 adsorption of gases as they flow through a bed of broken 24 25 coal, like the goaf. I had seen some reference particularly to carbon monoxide and to ethylene. 26 Would you be able to share with us what this concept is of adsorption 27 28 of these gases and what the impact is on the monitoring for signs of spontaneous combustion? 29 I don't have a lot of experience with that, and 30 Α. 31 I haven't - I'm not up to date with the research in that area, so I'm not in a position to give anything meaningful, 32 to comment on that at the moment. 33 34 35 MR CLOUGH: Fair enough. No more questions from me. 36 37 THE CHAIRPERSON: Thank you. Might Mr Muller be excused? 38 MR HUNTER: May it please, yes. 39 40 41 THE CHAIRPERSON: Mr Muller, thank you for your attendance. You are excused. 42 43 <THE WITNESS WITHDREW 44 45 46 MR HUNTER: That is all we have by way of evidence 47 arranged until Monday.
